The latest edition of the AI in Education Knowledge Base is available online at https://edtechdev.github.io/aied/.

AI in Education Knowledge Base

1. Introduction 14
    1.1. Navigating the site 14
    1.2. Chat with the knowledge base 14
    1.3. Recommended starting points by audience 14
    1.4. What is in the knowledge base 15
2. Use This Knowledge Base with Your Own AI Assistant 16
3. Foundations of AI in education 19
    3.1. Essentials 19
        3.1.1. AI in Education 20
        3.1.2. AI Literacy 30
        3.1.3. Information and Media Literacy 55
        3.1.4. Agentic AI 60
        3.1.5. Cognitive Offloading 75
        3.1.6. Cognitive Surrender 97
        3.1.7. Framing AI Use for Students 104
        3.1.8. Reducing AI Misuse 110
        3.1.9. Academic Integrity 119
        3.1.10. Teaching 139
        3.1.11. Teacher AI Competency 157
        3.1.12. Learning Design 171
        3.1.13. Educational Development 181
    3.2. The field 191
        3.2.1. History of AI in Education 192
        3.2.2. Interpreting and Applying AIEd Research 198
        3.2.3. Limitations in AIEd Research 206
        3.2.4. Philosophy of AI in Education 215
        3.2.5. Theories and Frameworks 221
        3.2.6. Theory Development in AI in Education 228
    3.3. Cross-cutting themes 236
        3.3.1. Human AI Collaboration 237
        3.3.2. Learner Agency 250
        3.3.3. Learner Identity 263
        3.3.4. Design Thinking 269
        3.3.5. Curriculum Design 273
        3.3.6. Critical Thinking 281

3.3.7. Computational Thinking 290

3.4. Theories and frameworks (Foundations of AI in education) 295

3.4.1. SAMR Model 296

3.4.2. Technological Pedagogical Content Knowledge (TPACK) 301

4. Learning and instruction 310

4.1. Core pedagogies 310

4.1.1. Pedagogies and Teaching Strategies 311

4.1.2. Pedagogical Patterns 318

4.1.3. Active Learning 332

4.1.4. Collaborative Learning 339

4.1.5. Project-Based Learning 349

4.1.6. Problem-Based Learning 354

4.1.7. Productive Failure 360

4.1.8. Inquiry-Based Learning 366

4.1.9. Experiential Learning 371

4.1.10. Game-Based Learning 376

4.1.11. Learning by Teaching 381

4.1.12. Scaffolding 388

4.1.13. Socratic Method 399

4.1.14. Critical Pedagogy 406

4.1.15. Pedagogical Partnerships 412

4.1.16. Storytelling in Education 419

4.1.17. Online Teaching and Learning 422

4.1.18. Video in Education 433

4.2. Learning theories and processes 438

4.2.1. Learning Theories 439

4.2.2. Behaviorism 447

4.2.3. Constructivism 452

4.2.4. Cognitive Psychology 461

4.2.5. Sociocultural Learning 466

4.2.6. Distributed Cognition 471

4.2.7. Situated Learning 476

4.2.8. Embodied Learning 480

4.2.9. Community of Inquiry 485

4.2.10. Self-Regulated Learning 490

4.2.11. Self-Determination Theory 505

4.2.12. Motivation 510

4.2.13. Self-Efficacy 518

4.2.14. Self-Directed Learning 527
4.2.15. Metacognition 531
4.2.16. Reflection 544
4.2.17. Desirable Difficulties 553
4.2.18. Transfer of Learning 561
4.2.19. Prior Knowledge 567
4.2.20. ICAP Framework 572
4.2.21. Misconceptions about AI 578
4.2.22. Refutation Text 586
4.2.23. Activity Theory 590
4.2.24. Retrieval, Spacing and Interleaving 595
4.3. Learner engagement and experience 601
4.3.1. Student Engagement 602
4.3.2. Help-Seeking 614
4.3.3. Social-Emotional Learning 624
4.3.4. Well-Being 631
4.3.5. Creativity 638
4.3.6. Student-AI Interaction 645
4.3.7. Problem Solving 652
4.3.8. Mastery Learning 657
4.3.9. Anxiety and Stress 662
4.3.10. Student Experience 672
4.3.11. Student Support and Success 680
4.3.12. Social Norms of AI Use 687
4.4. Lifelong and professional learning 692
4.4.1. Career Development and Readiness 693
4.4.2. Lifelong Learning 699
4.4.3. Workplace Learning 703
5. Technologies and techniques 709
5.1. Models and techniques 709
5.1.1. Technologies 710
5.1.2. Machine Learning 715
5.1.3. Generative AI 721
5.1.4. Large Language Models (LLMs) 729
5.1.5. RAG (Retrieval-Augmented Generation) 735
5.1.6. Prompt Engineering 739
5.1.7. LLM Training and Fine-Tuning 748
5.1.8. Vibe Coding 761

5.1.9. Multimodal AI 767
5.1.10. Speech and Voice Technologies 776
5.1.11. Visualization 785
5.1.12. Educational NLP 790
5.1.13. Reinforcement Learning 796
5.1.14. Knowledge Graph 800
5.1.15. Robots in Education 805
5.1.16. Conversational AI 812
5.1.17. Simulation 820
5.1.18. Virtual and Augmented Reality 827
5.2. Learner modeling and adaptive systems 832
5.2.1. Learner Modeling and Adaptive Instruction 833
5.2.2. Knowledge Tracing 841
5.2.3. Cognitive Diagnosis 848
5.2.4. Simulating Students 855
5.2.5. Intelligent Tutoring 866
5.2.6. Adaptive Learning 882
5.2.7. Personalized Learning 890
5.2.8. Recommender Systems and Learning Paths 899
5.2.9. Pedagogical Agent 907
5.2.10. Affective Tutoring 915
5.2.11. Affective Computing 920
5.2.12. Sensor and Gaze Analytics 925
5.2.13. AI Avatars and Synthetic Instructors 931
5.2.14. Human-in-the-Loop 938
5.2.15. Learning Analytics 948
5.3. Platforms, openness and adoption 958
5.3.1. Technology Adoption Models 959
5.3.2. Open Education 968
5.3.3. Open Source 974
5.3.4. Edtech Platform 981
6. AI in the disciplines 988
6.1. Subject areas 988
6.1.1. AIEd in the Disciplines 989

7.1.1. K-12 1171
7.1.2. Early Childhood Education 1181
7.1.3. Higher Education 1188
7.1.4. Adult Learners 1198
7.1.5. Vocational Education and Training 1203
7.1.6. Special Education 1209
7.1.7. Teacher Education 1214
7.2. Bands and comparisons 1225
7.2.1. Levels of Education 1226
8. Assessment and measurement 1232
8.1. Assessment and feedback 1232
8.1.1. Assessment 1233
8.1.2. Evaluative Judgment 1242

8.1.3. Feedback 1251
8.1.4. Feedback Literacy 1265
8.1.5. AI Feedback Quality 1272
8.1.6. Formative Assessment 1283
8.1.7. Summative Assessment 1294
8.1.8. Authentic Assessment 1300
8.1.9. Process-Oriented Assessment 1309
8.1.10. Group Work 1316
8.1.11. E-Portfolio 1323
8.1.12. Peer Assessment 1327
8.1.13. Self-Assessment 1336
8.1.14. Oral Assessment 1343
8.1.15. Automated Assessment 1349
8.1.16. Automated Essay Scoring 1364
8.1.17. Automated Question Generation 1371

8.2. Measurement and validity 1377

8.2.1. Assessment Validity 1378
8.2.2. Psychometrically Aware AI 1394
8.2.3. Educational Measurement 1399
8.2.4. Item Response Theory 1413
8.2.5. Self-Report Measures 1419
8.2.6. AI Detection 1429
8.2.7. Remote Proctoring 1440
8.2.8. Learning Gains 1446

9. Research methods and evaluation 1457

9.1. Research methods 1457

9.1.1. Research Methods in AIED 1458
9.1.2. AI-Assisted Educational Research 1472
9.1.3. Qualitative Research 1482
9.1.4. Quantitative Research 1489
9.1.5. Mixed-Methods Research 1495
9.1.6. Design-Based Research 1499
9.1.7. Usability Research 1504
9.1.8. RCT 1508
9.1.9. Meta-Analysis and Systematic Review 1513
9.1.10. Latent Profile Analysis 1526
9.1.11. Network Analysis 1531

9.2. Evaluation of AI systems 1536

9.2.1. AI Ed Evaluation 1537

9.2.2. Benchmark 1547

10. People 1554

10.1. Roles and audiences 1554

10.1.1. Administrators 1555

10.1.2. Educational Technology Developers 1559

10.1.3. Learners 1565

10.1.4. Librarians 1572

10.1.5. Parents and Families 1577

10.1.6. Stakeholders 1584

11. Institutions and policy 1589

11.1. Institutions 1589

11.1.1. Educational AI Policy 1590

11.1.2. AI Governance 1602

11.1.3. Change Management 1613

11.1.4. AI Regulation in Education 1619

12. Equity, ethics, and responsible use 1624

12.1. Equity and access 1624

12.1.1. Equity 1625

12.1.2. Differential Effects Across Learner Groups 1639

12.1.3. Digital Divide 1648

12.1.4. Bias Mitigation 1655

12.1.5. Culturally Relevant Pedagogy 1662

12.1.6. Multilingual Learning 1668

12.1.7. Inclusive Learning 1672

12.1.8. Accessibility 1679

12.1.9. Assistive Technology 1685

12.1.10. Neurodiversity 1689

12.1.11. Universal Design for Learning 1694

12.1.12. Global South 1699

12.2. Ethics and responsibility 1704

12.2.1. Ethics 1705

12.2.2. Automation Bias 1714

12.2.3. AI Misuse and Learning Harm 1721

12.2.4. Legal Issues and Risks 1727

12.2.5. AI Use and Disclosure Statements 1734
12.2.6. Guardrails 1741
12.2.7. Privacy 1748
12.2.8. Hallucination Risk 1754
12.2.9. AI Sycophancy 1759
12.2.10. Trust 1765
12.2.11. Trust Calibration 1774
12.2.12. Explainable AI 1786
12.2.13. Sustainability 1793
12.2.14. Pedagogical Safety 1797

13. Frequently Asked Questions 1803

13.1. Start here 1803

13.1.1. What Are the Top 10 Findings from AI in Education Research That Instructors Should Know About? 1804
13.1.2. How Can We Address Common Misconceptions About AI in Education? 1812

13.2. Course and institutional policy 1826

13.2.1. How Do I Write a Course AI Policy and Communicate It to Students? 1827
13.2.2. How Do We Write and Implement an Institutional AI Policy? 1834
13.2.3. What Competencies Do Faculty Need in Regard to AI? 1841
13.2.4. How Do I Design Faculty Development for AI That Actually Changes Practice? 1846

13.3. Designing courses and activities 1852

13.3.1. How Should AI Be Designed Into the Learning Experience? 1853
13.3.2. How Should We Design and Facilitate Asynchronous Online Courses When AI Can Do the Work? 1857
13.3.3. How Should I Handle AI in Group and Collaborative Assignments? 1866
13.3.4. How Should I Incorporate AI Literacy into My Course? 1872
13.3.5. How Can AI Save Me Time as an Instructor? 1878
13.3.6. How Can AI Agents Support Students and Instructors? 1882

13.4. Assessment, feedback and integrity 1884

13.4.1. How Do I Redesign Assessment So That a Grade Still Tells Me Something Defensible About What the Student Knows or Can Do? 1885
13.4.2. Can I Use AI to Grade Student Work Fairly and Reliably? 1890
13.4.3. How Do I Check Whether AI-Generated Quiz and Exam Questions Are Actually Good? 1894
13.4.4. How Can AI Help Me Give Better Feedback at Scale? 1898
13.4.5. How Can I Reduce AI Cheating in My Course? 1904
13.4.6. Should We Use AI Detectors? 1910
13.4.7. What Are Best Practices for Writing Instruction in the Context of AI? 1919

13.5. How students learn and use AI 1927

13.5.1. Does Using AI Actually Help My Students Learn? 1928

13.5.2. How Is AI Impacting Students? 1935

13.5.3. How Do I Keep Students from Over-Relying on AI? 1939

13.5.4. What Does Personalized Learning Actually Mean, and When Does It Help? 1947

13.5.5. How Do I Teach Students to Verify AI Output? 1951

13.5.6. How Should I Use AI to Study and Learn Effectively? 1957

13.6. Particular learners, access and wellbeing 1962

13.6.1. How Can AI Support Multilingual Learners Without Misjudging Their Knowledge or Erasing Their Voice? 1963

13.6.2. How Can AI Support Disabled and Neurodivergent Learners in My Course? 1967

13.6.3. How Does AI Affect Student Anxiety and Well-Being, and What Can We Do? 1974

13.6.4. How Should Parents and Teachers Approach AI with Children Under 13? 1980

13.6.5. How Should AI in Education Research Incorporate Equity, Accessibility, Privacy, Ethics, and Pedagogical Safety? 1987

13.7. Careers and AI literacy 1990

13.7.1. What Should Students Learn for Careers Where AI Is Commonplace? 1991

13.7.2. What Is the Evidence on AI Literacy Interventions in Higher Education? 1995

13.8. Building and evaluating educational AI 1999

13.8.1. What Are Best Practices for Developing an Effective AI Tutor? 2000

13.8.2. What Are Best Practices and Tips for Designing Effective Educational AI Software? 2010

13.8.3. How Do We Train an AI Tutor to Guide Students Rather Than Answer Them? 2015

13.8.4. How Do We Make a Simulated Student Behave Like a Real Learner? 2020

13.8.5. How Can We Make AI Better at Supporting Learning in Our Own Subject? 2026

13.8.6. How Do We Know an Educational AI Is Working Correctly, Not Just Scoring Well? 2032

13.8.7. What Measures and Research Methods Can an Instructor Use to Evaluate AI-Related Interventions? 2037

13.9. Research practice 2039

13.9.1. How Can AI Assist with Educational Research? 2040

13.9.2. What Are Best Practices for Reporting and Interpreting AI in Education Research? 2045

13.9.3. What Are Notable Gaps in the Research Literature on AI in Education? 2051

14. Free Tools and Resources 2059

14.1. Software 2059

14.1.1. Claw-ED 2060

14.1.2. Code Viva 2061

14.1.3. DeepTutor 2062

14.1.4. Gemini Notebook 2064

14.1.5. LearnHarness 2066

14.1.6. OnMicro.AI 2068

14.1.7. OpenMAIC 2070

14.1.8. PAUSE: Patterns of AI Use Self-Examination 2072

14.1.9. Playlab 2073

14.1.10. Process Feedback 2075

14.1.11. Public AI Libraries 2077

14.1.12. Snorkl 2079

14.1.13. Vibes DIY 2080

14.2. Agent Skill 2081

14.2.1. Clarity 2082

14.2.2. Education Agent Skills 2083

14.2.3. Master Instructional Design 2084

14.2.4. Skills for Real Engineers 2085

14.2.5. idstack 2086

14.3. Prompt Or Gem Library 2087

14.3.1. EduGems 2088

14.3.2. The Pedagogical Promptbook 2089

14.3.3. Writing and Rhetoric Studies in the Loop: A GenAI Prompt Library 2090

14.4. Collection Of Tools 2091

14.4.1. DrawSplat 2092

14.4.2. FPDS Apps and Resources 2094

14.4.3. Learning Commons 2096

14.4.4. TeacherServer 2098

14.4.5. The ID Toolbox 2099

14.4.6. teacher.dev 2100

14.5. Collection Of Activities 2101

14.5.1. Pressing Prompts 2102

14.5.2. mglearn Classroom Resources 2103

14.6. Assessment Instrument 2104

14.6.1. The Institutional AI Readiness Pack 2105

14.7.1. LESSON.md 2106

14.7.2. LiaScript 2107

14.8. Ebook Or Guide 2108

14.8.1. AI + OER Case Studies: A DOERS Project 2109

14.8.2. AI Infused Assignment Playbook 2111

14.8.3. Building Intelligent Textbooks 2113

14.8.4. Campus AI Development 2115

14.8.5. Campus AI Framework 2117

14.8.6. Integrating AI in TVET: a practical guide for institutions 2119

14.8.7. Learning Design Wiki 2121

14.8.8. Student Guide to AI 2123

Introduction

Welcome to the AI in Education Knowledge Base, a free, public-domain resource on artificial intelligence in education for the people who teach, study, design, or administer it. It summarizes and synthesizes recent open-access educational research. An AI agent writes and updates the pages with editorial guidance from the site developer.

Navigating the site

Browse the index in the left sidebar, which is arranged by strand, open the concept index, or search for a topic. Article pages condense one paper into its purpose, methods, and findings; concept pages collect what the research says about one idea and link to the studies behind it. To start from a question, the FAQ covers what visitors ask first, such as course AI policy or whether to run AI detectors. To start from a tool, the resources page lists free tools and collections, with who made each one and what it costs. The map above groups the field into twelve strands, with AI in Education as the central node.

Chat with the knowledge base

The whole knowledge base is also published as machine-readable files, so you can point an AI chatbot or agent at it and get answers that cite the pages. The prompts are here. New pages go into the journal, which has an RSS feed. A weekly newsletter, the AIEd Research Weekly Update, says what those additions mean for instructors, developers, researchers, and administrators. To read offline, download the EPUB or the PDF.

Recommended starting points by audience

Start with the group that matches your role.

Essential concepts

AI literacy, misconceptions about AI, agentic AI, cognitive offloading, and how to interpret and apply this research, including why a single study rarely settles a question. The full list covers every strand.

Instructors

The changing teaching role, learning design, assessment, feedback, academic integrity, framing AI use and reducing misuse. For subject-specific tools and examples, see AI in your own discipline.

Developers

Building for education, the technologies underneath, intelligent tutoring, multimodal AI, learner modeling, and training and adapting a model for teaching.

Administrators

The administrator role, AI governance, institutional policy, legal issues and risks, and change management.

Researchers

Research methods in AIED, theories and frameworks, evaluating an AI in education intervention, educational measurement, measuring learning gains, and the cross-cutting limits of this evidence base.

What is in the knowledge base

Every page is dated, and the counts below reflect what is published right now; the “last updated” date at the end of the list is the most recent edit.

- 2032 articles
- 230 concepts
- 42 FAQs
- 40 resources
- last updated November 5, 2026

Use This Knowledge Base with Your Own AI Assistant

Point any AI chatbot or agent at this knowledge base and it answers from these pages instead of from its own memory. Copy the prompt below, paste it into your assistant as your first message, then ask your question. A good answer names the pages it drew on and links to them, so you can check the sources yourself.

Nothing to install. If you would rather skip the prompt, the ready-made assistants already know this material.

The prompt to copy

Paste this in first, before your question. It works with any chatbot or agent that can read a web page or take a pasted document. The prompt is longer than the box shows; the button copies all of it.

Then paste it into your assistant and ask your question.

You are a research assistant for AI in education. Use the AI in Education Knowledge Base (https://edtechdev.github.io/aied/) as your primary source.

1. Route before you read. The FAQ index at https://edtechdev.github.io/aied/faq/ maps questions to the pages that answer them, including “what does the research show” questions. The full catalog at https://edtechdev.github.io/aied/llms.txt is 1.3 MB, the concepts-and-FAQs file at https://edtechdev.github.io/aied/llms-concepts.txt is 4.0 MB, and llms-full.txt is 20.9 MB, so search them or fetch parts rather than loading them whole, and do not let a failed whole-file fetch stop you.
2. Ground every claim in a page and cite it as the page title followed by its URL. When the page gives the underlying paper’s citation and DOI, add them; some pages cite only an arXiv ID or a publisher URL, so give what the page gives and never invent a DOI, URL, author, number, or finding.
3. Synthesize across pages instead of leaning on one. Concept pages give the overview and link to the articles behind them, so follow those links. Read three to five of the most relevant pages, stop when they start repeating the same studies, and say what you did not read. If the knowledge base covers the topic only in a neighboring field, say so and answer by analogy.
4. Match the strength of the evidence. Controlled or randomized experiments that measure unassisted performance are strongest, then meta-analyses adjusted for publication bias, then reviews, then pilots, policy analyses, and opinion; one small study is not consensus. Tags, audience, level and confidence ratings live in each page’s Markdown source at https://raw.githubusercontent.com/edtechdev/aied/main/<section>/<slug>.md, not in the rendered page, so if you cannot check them, judge from how the article describes the study and say that is what you did.
5. Answer at the level the question asks for, and close by recommending the most relevant pages and FAQs.

Prefer the term “generative AI” over “LLM”. The knowledge base is updated regularly, and the journal page at https://edtechdev.github.io/aied/journal/ lists the newest additions.

Example: “What does the research say about AI feedback for student writing?” Check the FAQ index, read the most relevant writing and feedback pages plus the studies they cite, then answer with citations and links. ## How to use it {.unlisted}

1. **Copy the prompt** with the button above.
2. **Paste it into your assistant** as the first message. It will usually reply that it understands.
3. **Ask your question** in plain language, for example “what does the research say about AI feedback in large classes?” or “should we use AI detectors?”
4. **Check the links.** A good answer names the pages it used. If you get confident claims with no page names, reply “which page did that come from?” and ask it to try again.

This works best in assistants that can browse the web, since the prompt points them at pages to read. If yours cannot open links, attach the text of the knowledge base as well: download the full-text file once, upload or paste it into the conversation, and use the prompt alongside it. It is a single text file of 20.9 MB. Many chat products refuse a file that size, so there is also llms-concepts.txt, every concept and FAQ page in full at 4.0 MB. Reach for that one first: the concepts are the syntheses of what the research shows, the FAQs are the questions those syntheses answer, and each concept page links the papers behind it.

Technical notes for tools that want a URL instead of a prompt

- llms.txt: a catalog of every page, one line each, for tools that index a site before reading it
- llms-full.txt: the complete text of the knowledge base in one file, 20.9 MB
- llms-concepts.txt: full text of the concept and FAQ pages, 4.0 MB, for tools and chats that reject the larger file
- Sitemap: every page address
- RSS feed: new and updated pages

Ready-made assistants

If you would rather not set anything up, use one of these ready-made assistants:

- **AI in Education Advisor**, a Gemini Gem that answers from this knowledge base. Its custom instructions are public, and it was built from a static copy of the knowledge base, so it may lag behind the newest pages.
- **NotebookLM notebook**: a Google NotebookLM notebook built on the same material, with autogenerated reports, infographics, a podcast, slides, and a video.

What is in the knowledge base

Over a thousand research summaries cover tutoring and AI tutors, assessment and feedback, academic integrity, AI literacy, teacher and faculty development, equity and accessibility, privacy, policy and governance, and learning science topics such as cognitive offloading and learner motivation. Every summary ends with the full citation and a link to the original paper, so your assistant can pass the reference along.

Three kinds of page answer different questions: concept pages summarize what the research says about one idea and link to the studies behind it, article pages cover one paper at a time, and the FAQs answer practical

questions from instructors and administrators. Ask for a concept page when you want an overview, and for the articles behind it when you want the evidence.

Questions that are already answered

Many of the questions people ask an AI first have already been answered here by hand, with the research attached:

- How do I write a course AI policy and communicate it to students?
- How can I reduce AI cheating in my course?
- Should we use AI detectors?
- How should assessment be redesigned for the AI era?
- How do I keep students from over-relying on AI?
- How do we write and implement an institutional AI policy? The full list of FAQs is worth a look before you ask, and the prompt tells your assistant to check that list first.

Read the knowledge base offline

You can also download the knowledge base as an EPUB or PDF for an e-reader, phone, tablet, or computer. These offline editions contain the concept pages and FAQs, not the article summaries.

Foundations of AI in education

Essentials

AI in Education

> **AI in Education (AIED)** — the broad, interdisciplinary field that applies artificial intelligence to teaching and learning, and studies its design, use, evaluation, and consequences. As the knowledge base's umbrella concept, AI in education encompasses **AI for education** (using AI to improve instruction and assessment) and **education about AI** (developing AI literacy and critical understanding). It sits at the intersection of instructional technology, the learning sciences — the empirical research field that asks whether a learner changed rather than only whether a tool performed — computer science, educational policy, Ethics, and equity. This page is an introduction to the field and a map to every concept the knowledge base covers.

Questions to Consider

- 'AI in education' spans two directions: AI for education (using AI to improve teaching) and education about AI (building literacy and critical understanding). Which is more familiar to you, and which do you tend to overlook?
- The field's history is framed as a recurring tension between control and learner agency. As you watch AI tools being adopted, where do you notice that same tension playing out today?
- AI in education sits at the intersection of technology, learning science, policy, ethics, and equity. Which of those lenses do you naturally apply when evaluating an AI tool — and which are you likely to forget?
- This knowledge base organizes the field into strands: pedagogy, learning theories, technologies, disciplines, assessment, feedback, stakeholders, and governance. If you were mapping your own use of AI, which strand would you find yourself in?
- AIED includes teaching students to use AI critically as a goal in itself. In your context, is AI treated more as a subject to be taught or a tool to be used — and does that balance reflect what learners actually need?
- Students may learn AI literacy by using AI critically, not just by learning about AI. How might hands-on, critical use build understanding that passive instruction cannot?

Introduction

AI in education is the umbrella that all other concept pages collectively define. The knowledge base organizes the field into the major strands below, each linking to the relevant concept pages.

A landmark historical perspective, **Mishra et al.** trace AIED from cybernetics and the 1956 Dartmouth conference through cognitive tutors and Papert's constructionism, arguing that today's GenAI debates re-enact the field's foundational control-vs-Learner Agency tension.

How the knowledge base is organized: the umbrella pages

The knowledge base's concept coverage is anchored by several **umbrella pages** that group related concepts into navigable strands. These are good entry points for exploring the field:

- **AI in Education** — this page, the field's overview and map to all coverage.
- **AI literacy** — the umbrella for understanding, using, and critically evaluating AI, spanning prompt engineering, critical thinking, AI ethics, and responsible use. Alongside it, human–AI collaboration and agentic AI frame how people and AI work together.
- **Pedagogies and teaching strategies** — the umbrella for how teaching happens: the teaching methods and strategies AI operates within (active, collaborative, project-based, problem-based, experiential, game-based, Socratic, Scaffolding, and more), including the distinct context of online teaching and learning.
- **Learning theories** — the umbrella for how learning happens: the theoretical frameworks (Behaviorism, cognitivism, constructivism, sociocultural, cognitive, motivational) that shape AI design and evaluation.
- **Technologies** — the umbrella for the technical layer: the AI systems (LLMs, generative AI, Multimodal AI, robotics) and techniques (RAG (Retrieval-Augmented Generation), prompt engineering, reinforcement learning, model training, agentic orchestration) that power AIED. The learner-modeling family — knowledge tracing, cognitive diagnosis, simulating students, and the systems that consume them (intelligent tutoring, adaptive learning, personalized learning) — is grouped under the Learner Modeling and Adaptive Instruction umbrella within this technical strand.
- **AI in the disciplines** — the umbrella for how AI is applied across subject areas (mathematics, physics, language learning, computer science, writing, STEM, engineering, business, teacher education, health professions, and more) — and, past the academic subjects, the professional and applied strand that assesses demonstrated practice rather than correctness (nursing, information technology, vocational education and training, design education) — and educational levels (K-12, higher education, adult learning).
- **Assessment** (with formative, summative, authentic, oral, and automated strands) — the umbrella for how AI both assesses learners and reshapes assessment validity and integrity.
- **Feedback** — the umbrella for how feedback is generated, delivered, and used: the feedback loop, feedback quality, feedback literacy, and its assessment contexts (formative, peer, automated).
- **Stakeholders in AI education** — the umbrella for who the actors are: learners, teachers, learning designers, administrators, and policymakers.
- **AI ed evaluation** and **research methods** — the umbrellas for how we know whether AI works: efficacy studies, benchmarks, randomized controlled trials, meta-analysis, and learning gains as the core outcome measure. Readers should also weigh the cross-cutting limitations of this evidence.
- **AI governance**, **educational AI policy**, and **equity** — the umbrellas for the institutional, regulatory, and fairness layer (see also AI Regulation in Education and Privacy).

These umbrella pages are linked throughout the sections below; each strand below names both its umbrella and its constituent concepts.

Two dimensions of AI in education

AI in education research spans two interconnected directions:

- **AI for education** — using AI systems to enhance teaching, learning, assessment, and administration. This includes AI tutoring, adaptive learning, personalized learning, automated essay scoring, automated question generation, automated assessment, formative assessment, learning analytics, and feedback loops.
- **Education about AI** — teaching learners and educators to understand, use, and critically evaluate AI. The core is AI literacy, supported by prompt engineering, critical thinking, AI ethics, governance education, digital literacy, and responsible use.

These two dimensions are not separate: using AI well requires understanding it, and teaching about AI is enriched by using it. This human-AI collaboration is a central theme.

Foundations of AI in education

The field's cross-cutting and foundational concepts anchor the knowledge base's coverage and appear first in the sidebar. They open with an **Essentials** group — the concepts every reader should start with: the umbrella itself, misconceptions about AI, AI literacy, agentic AI, cognitive offloading, how AI use is framed for students, reducing AI misuse, academic integrity, teaching, learning design, and educational development. The **field** strand then covers the field's history, the cross-cutting limitations of the evidence base, its philosophy, the theories and frameworks map, and theory development. The cross-cutting themes — human–AI collaboration, learner agency, learner identity, design thinking, curriculum design, critical thinking, and computational thinking — cut across every strand, because the inaccurate mental models people hold about AI are upstream of misuse and under-calibrated trust.

Learning and instruction

How AI supports teaching and learning is the heart of the field. Key concepts include:

- **Core pedagogies:** pedagogies and teaching strategies — the umbrella for the knowledge base's teaching-methods coverage — along with pedagogical patterns (the tested sequences those methods resolve into), active learning, collaborative learning, group work, project-based learning, problem-based learning, productive failure, inquiry-based learning, experiential learning, game-based learning, learning by teaching, Scaffolding, the Socratic method, critical pedagogy, pedagogical partnerships, storytelling, learning design, online teaching and learning, and video in education.
- **Learning theories and processes:** the learning theories umbrella (Behaviorism, cognitivism, constructivism, sociocultural, distributed cognition, situated learning, embodied learning, community of inquiry) sits alongside learner-facing processes like self-regulated learning, self-determination theory, Motivation, Self-Efficacy, self-directed learning, Metacognition, desirable

difficulties, transfer of learning, prior knowledge, ICAP cognitive engagement, Reflection, refutation text, retrieval, spacing and interleaving, and activity theory.

- **Learner engagement and experience:** student engagement, Help-Seeking, social-emotional learning, Well-Being, Creativity, problem solving, mastery learning, and student–AI interaction shape how learners actually encounter and are affected by AI, while the social norms that settle around AI use decide how openly any of it can be discussed. Beyond the course, student support and success covers the institutional-side work — advising, outreach, referral, and the allocation of scarce support — where AI reliably moves task completion but not persistence or graduation.

Technologies and techniques

The Technologies page is the umbrella for the technical layer:

- **Models and techniques:** generative AI, large language models, retrieval-augmented generation, multimodal models, educational NLP, reinforcement learning, knowledge graphs, robots in education, conversational AI, Simulation, and LLM training and fine-tuning. The underlying methods matter too: machine learning is where these systems are built, speech and voice technologies carry spoken tutoring and language practice, Visualization covers dashboards and visual analytics for learners and instructors, and virtual and augmented reality hosts immersive practice whose visual layer the model can now generate. Newer interaction styles belong here too — most prominently vibe coding, the natural-language-driven workflow in which the user specifies a program by prompting an LLM and judges the resulting behavior rather than reading or editing source. That reframes programming as an act of expression and verification and lowers the barrier to end users building their own tools. Integration-depth frameworks such as SAMR and adoption theories such as TAM classify how deeply AI is taken up and how much it transforms the task.
- **Learner modeling and adaptive systems:** the technical systems that represent and adapt to the learner are grouped under the Learner Modeling and Adaptive Instruction umbrella — knowledge tracing, cognitive diagnosis, simulating students, intelligent tutoring, adaptive learning, personalized learning, recommender systems and learning paths, pedagogical agents, affective tutoring, affective computing, sensor and gaze analytics, AI avatars and synthetic instructors, human-in-the-loop AI, and learning analytics. These sit at the technical layer because they are the AI systems themselves, distinct from the pedagogies they enact.
- **Platforms, openness and adoption:** the layer around the model, where a teaching resource is licensed, hosted and paid for rather than built. Open education covers teaching with openly licensed content and the pedagogy that treats students as producers of it, which is where the license and adaptation questions that generated material now raises are argued. It sits beside openness in the software sense, platform-level analysis in edtech platforms, and the adoption research carried by TAM.

AI in the disciplines

AI is applied across disciplines and educational levels. The knowledge base's overview of AIEd in the disciplines maps subject-area coverage — alongside learning sciences, which is not a taught subject but the cross-cutting research field that studies learning itself and takes subject matter as one variable among others:

- **Subject areas:** mathematics, statistics and data science, physics, chemistry, biology, computer science, engineering, STEM, writing, reading education, language learning, English education (EAP/EFL/ESL), library and information science, science education, environmental education, business, economics, and management, humanities and social sciences, civic and political education, arts, design and media education, medical and health professions, legal education, and the professional and applied strands — nursing, information technology, vocational education and training, and design education.

Levels and contexts

The same AI tool meets very different settings, and the knowledge base separates the educational level from the pedagogy so that findings do not silently transfer across them: K-12 schools, early childhood and elementary education, higher education, adult learning, vocational education and training, special education, and teacher education. Domain-adjacent concepts that cut across levels include universal design for learning, Neurodiversity, multilingual learning, and social-emotional learning.

Assessment and measurement

AI transforms both how we assess learners and how we evaluate AI systems themselves:

- **Assessment and feedback:** Assessment, formative assessment, summative assessment, authentic assessment, e-portfolio, Feedback and feedback literacy, AI feedback quality, peer assessment, oral assessment, automated assessment, automated essay scoring, and automated question generation. Because a model can now produce plausible finished work on demand, the knowledge base foregrounds the capability that remains the learner's own: evaluative judgment, the capacity to appraise the quality of one's own work, peers' work, and AI output against reasoned criteria. It is the construct several feedback and authentic-assessment studies converge on — the hybrid feedback condition outperforming direct AI feedback in a multisite experiment, the sustainability gap in AI formative feedback, and the practical move of assessing the decisions students make rather than only the artifact — and it is a core reason AI-era redesign shifts from detection toward tasks whose integrity survives inspection. Group work is likewise assessed along both process and product, where teams must negotiate whose and what kind of AI engagement counts as acceptable.
- **Measurement and validity:** assessment validity, psychometrically aware AI, educational measurement, item response theory, self-report measures (the instrument behind a large share of this evidence, and a recurring limitation), AI detection, remote proctoring, and academic integrity.

Research methods and evaluation

How we know whether AI works is its own strand, and the knowledge base treats it as one:

- **Research methods:** research methods in AIED as the umbrella, with qualitative, quantitative, mixed-methods, design-based, and usability approaches, plus randomized controlled trials, meta-analysis and systematic review, and network analysis.

The field's own research work is now a subject in its own right. AI-Assisted Educational Research covers AI used as an instrument for literature search, screening, qualitative coding, analysis, and writing, including practitioner research such as the scholarship of teaching and learning. It stays distinct from the designs used to study what AI does to learners.

- **Evaluation of AI systems:** AI ed evaluation and benchmarks for judging a system's capability, with learning gains as the outcome that matters, and the cross-cutting limitations of this evidence and how to read a single study as the cautionary counterweight.

People

AI in education changes the roles of every stakeholder. The knowledge base's Stakeholders in AI education page is the umbrella covering all of them:

- **Learners:** student experience, career development and readiness, and AI anxiety and stress shape how students encounter AI.
- **Families and communities:** parents and families are the audience schools address most often about AI and the one with the least research behind the guidance, so their concerns belong in the stakeholder picture rather than outside it.
- **Instructors and teaching frameworks:** teacher AI competency, technological pedagogical content knowledge (TPACK), SAMR, and educational development address educator preparation and support.
- **Builders:** Educational Technology Developers — the product designers, software developers, learning engineers and analytics designers who turn a model capability into something an institution can procure. They are a distinct audience from the practitioners and administrators above, and they sit outside the institutions that adopt their tools, which is why defaults, co-design and post-funding maintenance appear in this knowledge base as pedagogical questions rather than commercial ones.

Institutions and policy

The institutional layer is where AI decisions are actually made and defended: administrators and institutional leaders, educational AI policy, AI governance, change management as the work of making an adoption stick, AI regulation, and the procurement and platform questions that follow from technology adoption, open source, and edtech platforms, alongside professional and lifelong learning and professional training.

Equity, ethics, and responsible use

Fairness, access, and responsibility are central to AI in education:

- **Equity and access:** Equity, differential effects across learner groups (the question of who a finding holds for), digital divide, bias mitigation, culturally relevant pedagogy, multilingual learning, inclusive learning, Accessibility, assistive technology, Neurodiversity, universal design for learning, and Global South studies.
- **Ethics and responsibility:** AI ethics, AI misuse and learning harm, legal issues and risks, AI use disclosure, Guardrails, Privacy, hallucination risk, AI sycophancy, Trust, trust calibration, automation bias, reducing AI misuse, how AI use is framed for students, pedagogical safety, Sustainability, and cognitive offloading.

A systematic review of the field's ethics literature (Agarwal et al. 2026, 25 articles) consolidates AIED ethics into six main ethical values — non-discrimination, data stewardship, human oversight, goodwill, explicability, and educational aptness — and maps the ethical norms onto a stakeholder-by-value matrix. It finds end users largely passive in the ethical literature (student voices essentially absent) and calls for integrating ethics into AIED design and a greater focus on the educational (pedagogical) dimension of AIED ethics.

Emergent and cross-cutting themes

Several themes cut across the field:

- **Trust and critical use:** Trust, trust calibration, AI sycophancy, critical thinking, cognitive offloading, critical pedagogy, and reducing AI misuse (see also how AI use is framed for students). How learners and teachers decide to adopt and rely on AI is modeled by technology acceptance research, while Global South studies foreground equity and cultural context in adoption. Empirically, how AI explains itself shapes this trust: Feldman-Maggor et al. (2025) showed that explainable AI builds teachers' trust in AI recommendations through understandability, with domain-driven (curricular-language) explanations trusted and accepted more than data-driven feature-importance output.
- **The evolution of the field:** the knowledge base traces AI in education from early intelligent tutoring systems and knowledge tracing to LLM-driven tutoring, agents, and agentic AI — a rapid shift from tool-centric studies to sociotechnical frameworks (design thinking, curriculum design, institutional change), and from hand-authored systems to user-driven workflows in which a learner or non-programmer specifies behavior in natural language (vibe coding). Rismanchian & Doroudi formalize this trajectory with their AI×Ed framework, tracing papers across four decades of proceedings to show that the field moved from a diverse mix — including substantial research treating AI as an analogy to human intelligence and learning — toward a near-exclusive focus on applied, data-driven, researcher-facing uses, a turn that the rise of LLMs now appears to partly reverse (three of the four "AI-as-analogy" papers at AIED 2024 were LLM-based).
- **Emotion, anxiety, and career futures:** AI induces and shapes emotional responses — AI anxiety and stress spanning proctoring surveillance, integrity fears, and career displacement — while

career development and readiness addresses how education prepares learners for an AI-disrupted labor market (see also Well-Being).

Field maturity

The knowledge base reflects a field in rapid evolution — from early intelligent tutoring systems to LLM-driven tutoring and agentic AI; from detection-focused academic-integrity tools to assessment redesign; from tool-centric studies to sociotechnical and equity-focused frameworks. The evidence base increasingly emphasizes rigorous research methods, evaluation, experimental designs, and long-term outcomes.

Connections

AI in education connects to every concept in the knowledge base — it is the field that all other concept pages collectively define. Use this page as a starting point to navigate the full knowledge base.

Common Misconceptions

“AI in education is one field with one evidence base.” It is an umbrella over distinct strands — disciplines, levels, assessment, research methods, institutions, equity — that differ in their methods, their outcome measures and their maturity. A finding from one strand does not transfer to another, which is why the knowledge base is organized this way rather than as a single literature.

“A tool that improves course outcomes improves student success.” The institutional strand shows the opposite pattern: in student support and success, AI **reliably moves task completion but not persistence or graduation**. An intervention can win every in-course measure and leave the completion outcome flat.

“Technology performance is evidence about learning.” The field sits at the intersection of instructional technology and the learning sciences, and the distinction between the two is exactly this: whether a learner changed, rather than only whether a tool performed. A demonstration is a claim about the tool.

“Because AI is general-purpose, a finding anywhere applies everywhere.” Generality of the technology does not create generality of the evidence. The discipline, level and context strands exist because the same tool behaves differently across them, and an unchanged finding carried across a boundary is an extrapolation.

“The field’s maturity can be read off its publication volume.” Volume and maturity diverge; the research-methods strand documents recurring design weaknesses that volume does not fix, and frameworks multiply faster than they are tested.

Connected Concepts

- Pedagogical Patterns — The tested sequences that operationalize the field’s pedagogies
- AI Literacy — umbrella: understanding, using, and evaluating AI
- Automation Bias — the reader-side failure: accepting an automated judgment without checking it
- Human AI Collaboration — umbrella: how people and AI work together
- Pedagogies and Teaching Strategies — umbrella: teaching methods and strategies
- Learning Theories — umbrella: how learning happens

- Technologies — umbrella: models, techniques, and systems
- AIEd in the Disciplines — umbrella: AI across subject areas and levels
- Assessment — umbrella: how AI assesses learners and reshapes validity
- Feedback — umbrella: how feedback is generated, delivered, and used
- Stakeholders — umbrella: who the actors are
- Learners — umbrella: the learner-side concepts (experience, identity, agency, interaction, learner models)
- AI Ed Evaluation — umbrella: how we know whether AI works
- Research Methods in AIED — umbrella: efficacy research methods
- AI-Assisted Educational Research — AI-Assisted Educational Research
- AI Governance — umbrella: the institutional and regulatory layer
- Educational AI Policy — umbrella: policy, guidance, and implementation
- Equity — umbrella: fairness, access, and inclusion
- Learning Sciences — the empirical field behind AIED
- Ethics — the ethical dimensions of AI in education
- Misconceptions about AI — the mental models people bring to AI
- Interpreting and Applying AIEd Research — reading a study, and carrying a finding into practice
- Limitations in AIEd Research — cross-cutting limits of the evidence base
- Meta-Analysis and Systematic Review — what the reviews and meta-analyses establish
- History of AI in Education — how the field evolved
- Philosophy of AI in Education — the philosophical foundations
- Theories and Frameworks — the map of theory and framework nodes
- Theory Development in AI in Education — building and revising theory
- Sensor and Gaze Analytics — umbrella: sensing learners through gaze, EEG and wearable signals
- AI Avatars and Synthetic Instructors — umbrella: synthetic humans teaching, tutoring, simulating and assessing
- Civic and Political Education — subject area: literacy for public life, with a thin evidence base

Connected FAQs

- What Are the Top 10 Findings from AI in Education Research That Instructors Should Know About?

AI Literacy

> **AI literacy** — the knowledge, skills, and critical dispositions needed to understand, evaluate, and effectively use AI Technologies in educational contexts. AI literacy spans foundational understanding of how AI works, practical competence in using AI tools, critical evaluation of AI outputs, and ethical awareness of AI's societal implications.

Questions to Consider

- What does it mean to be 'AI literate'? Is it knowing how to use the tools, understanding how they work, or being able to critically evaluate their output — and which matters most for your own goals?
- Self-reported AI literacy diverges sharply from measured performance — teachers overestimate their skills by about 40%. How confident are you in your own AI skills, and what evidence would you trust to actually test that confidence?
- AI literacy is described as a metacognitive social practice, not a checklist of skills. Because LLMs are probabilistic and opaque, what does it mean to 'critically evaluate' output when you can't see inside the model?
- There's a tension between critical-use literacy for academic settings and workflow-integration literacy for employment — educators and employers value different skills. Which kind of AI literacy is your context actually teaching?
- Technical AI-literacy training alone, without self-efficacy and self-regulation support, can actually increase dependency on AI. How could learning to use AI make you more reliant on it rather than more capable?
- AI literacy is also a recognition skill: spotting when an AI is agreeing with you because it's being sycophantic versus because you're right. Have you ever caught an AI just telling you what you wanted to hear?

Introduction

AI literacy has rapidly emerged as a core competency for learners, educators, and institutions as Generative AI becomes embedded in education. Unlike general digital literacy, AI literacy requires understanding probabilistic systems that can hallucinate, exhibit bias, and shift Learner Agency from human to machine — making Critical Thinking and Over-Reliance central to the construct.

Dimensions of AI literacy

Output-directed and system-directed literacy are separate dimensions with evidence for the split. Bergdahl (2026) found 47 Swedish year 7 students strong on source evaluation (Mdn = 3) and governance (Mdn = 4, 57% at the highest option) but weak on **data privacy (Mdn = 1, 66% at the lowest)** and **algorithmic manipulation (Mdn = 2, 47% at the lowest)**. Grouped by domain, the median output-directed

score was 3 against 2 for system-directed. The finding is not that these students lacked literacy but that **literacy in reading AI output did not extend to questioning how that output was produced** — a distinction with direct consequences for how a program is scoped and measured, since a single score would average both registers and report a middle that describes neither.

AI literacy research in this knowledge base spans four interconnected dimensions:

Frameworks increasingly trace how these dimensions are enacted in practice: Dai & Chan (2026) show how postgraduate researchers enact all four dimensions when using Generative AI across the research workflow and scaffold research-specific responsible-use guidelines from them, while Şan & Orhan Karsak (2026) use Word-Association mapping to show that Turkish undergraduates' AI cognition is instrumentally "black-box" dominated, with ethical-governance concepts structurally isolated ($\tau=-0.819$) — evidence that credential design must deliberately bridge experiential tool use and ethical frameworks.

Experts converge on the competencies and not on where they sit. Eleven experts rated a nine-competency, three-domain framework's content favorably yet disagreed on competency placement ($M = 3.73$, $SD = 1.19$, $IQR = 1.50$) while endorsing non-exclusive domain relations ($M = 4.45$, $SD = 0.52$), reading the domains as functional roles rather than fixed buckets (Lee, Son and Hong (2026)).

The demand depends on what the student and the system are jointly doing. Literacy frameworks usually describe one generic set of competences, but what a GenAI-supported activity actually requires varies with how epistemic work is distributed inside it. Sun, Dohn and Rehm (2026) classified 102 empirical higher-education studies against Strobel et al.'s taxonomy of GenAI applications and found Assistant and Enabler entanglements dominating at 42.16% of the corpus each, while Generator, Reimaginator and Synthesizer together accounted for under a fifth — a skew they attribute to institutional legitimacy rather than model capability, since the same models support all five. Reading each type through Dohn's three context levels (domain-internal, activity-internal, activity-framing) shows demands cohering for Assistant work and fracturing for the marginal types, where what the activity asks of students diverges from what the institution recognizes as legitimate competence. Their conclusion moves literacy away from tool fluency altogether: GenAI literacy is the capacity to recognize how epistemic work and responsibility are distributed in a given entanglement, and to act appropriately within it.

Different dimensions predict different things. Averaging AI literacy into one score hides which competence does what. In a task-based study of 162 university students writing a research abstract with an assistant built on DeepSeek V3, only the Use and Apply dimension independently predicted abstract quality ($\beta = 0.206$, $p = 0.042$), and only Know and Understand independently predicted lower perceived mental load ($\beta = -0.344$, $p = 0.001$). The total score predicted both, but neither it nor any dimension predicted Motivation or Self-Efficacy (Chen et al. (2026)). A student can be competent enough to produce a better text and still find the task as demanding, which is an argument for assessing and teaching the dimensions separately instead of reporting one literacy number.

Foundational knowledge: Understanding what LLMs are, how they differ from rule-based systems, and their fundamental limitations. This includes awareness of model capabilities, training data biases, and the distinction between task-specific AI and general-purpose models. Research in Prompt Engineering examines how understanding prompt mechanisms affects effective AI use.

Practical competence: The ability to use AI tools effectively — from Prompt Engineering to interpreting outputs. Studies of student GenAI usage patterns reveal that tool access alone doesn't produce competence;

structured practice and Scaffolding are essential. The vibe coding framework shows how K-12 teachers can develop practical AI literacy through guided tool creation. Miles, Haber-Curran and Arar (2026) argue that this dimension has a part optimization training misses: prompt literacy, as distinct from prompt engineering, treats prompting as a rhetorical and ethical act, so instruction that only tunes outputs for better performance leaves the ethical and epistemological dimensions of LLM use untouched.

Critical evaluation: The capacity to assess AI outputs for accuracy, bias, and appropriateness. Research on literacy assessment shows a 40% gap between self-reported and performance-based AI literacy — people consistently overestimate their evaluation skills. That divergence is the clearest case in the knowledge base of a self-report measure failing to track the competence it names. This connects to Over-Reliance research showing that students who Trust AI uncritically learn less. Recent conceptual work pushes evaluation toward *verification*: the PEARLS framework (Wang) treats AI output as a provisional knowledge claim whose warrant must be assembled and examined across six dimensions (Process, Evidence, Access, Reproducibility, Legitimacy, Source), and advances **verification-driven learning** as the mechanism by which learners build expertise while checking AI claims. Complementing this, the student-centered responsible-use framework (Alsammani) offers ten student-facing guidelines across Learning and Growth, Ethics and Integrity, and Awareness and Safety pillars that externalize metacognitive prompts at the point of decision. For secondary learners, the AI-Assisted Research Competency (AARC) framework (Beau, Flaquière & Lazar 2026) grounds this in virtue epistemology and AI intuition, defining research literacy as conducting inquiry with AI without surrendering authorship, judgment, verification, or responsibility — operationalized as an analytic rubric and a verify–cite–reflect commitment routine. At the Assessment end, Saleh (2026) proposes a *human capability test* that turns evaluation into a design principle: ask what a student must demonstrate independently, what can be strengthened through AI augmentation, and what the student must verify, defend, and take responsibility for.

Disciplinary verification raises the same bar further. Vega-Baudrit and Rivera Alvarez (2026) argue that in university chemistry the core AI literacy demand is representational translation across Johnstone's macroscopic, submicroscopic and symbolic domains, because an output can be locally persuasive in one domain while contradicting charge balance, a mechanism or a safety limit in another. Their remedy is verification-centered integration: make verification an assessed activity, keep prompt logs and revision histories as reasoning traces, and treat prompting as an epistemic act that specifies constraints, assumptions and adequacy criteria, with students identifying a false assumption or justifying rejection of a generated answer.

Ethical and institutional awareness: Understanding AI's broader implications — from Academic Integrity to Equity to Privacy. AI literacy at the institutional level involves policy development, Educational Development, and governance frameworks — institutional AI literacy is a matter of policy as much as pedagogy. The EPIQ-AI framework frames institutional AI literacy as a sociotechnical alignment challenge, not just individual training.

Security is a literacy domain of its own. Yocam, Vaidyan and Kalathas (2026) argue that neither AI-literacy nor cybersecurity frameworks treat operating securely in an AI-mediated school as a competency in its own

right, and only 34.5% of US teachers report a school AI policy (AI Security Literacy: Ecosystem-based Competency Framework and K-12 Learning Platform).

- **AI literacy as a governance capacity for sustainable development.** Islam, Morshed, and Islam (2026) reconceptualize AI literacy as a governance-oriented capacity rather than a purely educational or technical skill, linking it to all seventeen UN Sustainable Development Goals. Their six-level **AIRE Taxonomy** (Recognize → Comprehend → Apply → Analyze → Integrate → Govern) extends Bloom's hierarchy by adding ethical synthesis and strategic foresight, positioning advanced competencies (Analyze–Govern) as the pathway from foundational literacy to institutional and policy-level governance — an "18th SDG" heuristic that treats literacy as a cross-cutting cognitive and ethical bridge. A survey of 300 professionals in a national context found strong technical awareness but limited ethical and governance readiness, with **ethical reasoning and reflective thinking the strongest predictors of sustainable, trustworthy AI use** and governance literacy the strongest predictor of AI–SDG nexus awareness (β = 0.64). This empirically grounds the knowledge base's emphasis on critical-use literacy and ties AI literacy directly to Sustainability and policy integration. **The framework supply is now its own problem.** Fitsilis (2026) compared 16 institutionally endorsed AI competence frameworks for education and workforce development and found a shared core of ten competence areas but wide variation in structure, progression and implementation guidance — the practical difficulty is choosing among them, not a shortage.

The facets do not predict the same outcome. In a PLS-SEM survey of 475 design students across Europe, Asia, and Australia, ethical awareness predicted academic Well-Being (β = 0.324) but not perceived learning performance, while emotional adaptability was the strongest direct predictor of performance (β = 0.322) (Liang et al., 2026).

How AI literacy is developed

Research points to collaborative and active approaches as most effective. Rismanchian & Doroudi position AI literacy as more than applied skill: in their AI×Ed framework the learner is a distinct end user of AI (accessed through AI literacy and AI education), and they argue for renewed AI-literacy work that encourages reflection on learning itself — treating literacy as a route back into "AI as an analogy to human intelligence" research on how people learn, a strand the field largely abandoned. The ICAP Framework (Interactive → Constructive → Active → Passive) provides a useful taxonomy of cognitive engagement: students learn AI literacy best when they co-construct knowledge rather than passively receive information. Designers should select the mode that fits the learning goal and favor the deeper (constructive and interactive) modes where possible. Practical activities — designing prompts, evaluating outputs in groups, debating AI Ethics — outperform lectures.

Composition starts from lived experience — but concept depth needs scaffolding. Burriss et al. (2026) found that youth anchored abstract AI Ethics principles in systems they encounter daily — electronic "hall passes," school-regulated laptops, plagiarism detectors — with one group explaining that AI in schools "was personal to all group members," and 15 of 18 end-of-unit survey responses reported that making the video changed their understanding of AI ethics. The authors are explicit about the limit: composing did not by itself guarantee conceptual grounding — "informed consent" was translated as "We gotta approve," and some

terms (e.g., “failsafe”) were never explained, prompting them to plan deeper conceptual work in later iterations. Creative production develops AI literacy best when explicit conceptual Scaffolding accompanies the making rather than being assumed to emerge from it.

AI intuition as the experiential complement to literacy. A recurring gap is that K-12 frameworks assume learners approach AI through declarative, rule-based knowledge, when in practice they first develop a practical “feel” for how AI responds — experimenting with prompts, observing behavior, adapting strategies — before they can articulate formal principles. Beau & Lazar (2026) formalize this as **AI intuition**: an experiential, inductive, often tacit understanding that develops through iterative interaction with AI systems and supports context-sensitive judgment under uncertainty. Their **dual framework** situates AI literacy (structured, largely static competencies) alongside AI intuition (a dynamic learning process), mapping both across the standard dimensions — understand concepts, use tools, evaluate critically, apply ethically, reflect — so learners combine conceptual clarity and Guardrails (literacy) with the practical wisdom to trust-but-verify and decide when to disengage (intuition). Because intuition cultivates “expert observation” of AI (e.g. stress-testing prompts to find where a model fails), the authors argue it is a safeguard against over-reliance and critical-thinking erosion; it is distinct from Prompt Engineering (which optimizes outputs) in foregrounding *epistemic judgment*. This connects literacy to Experiential Learning, Constructivism, and developmentally grounded classroom practice, and points teacher preparation toward facilitating inductive exploration rather than only delivering concepts. **For young children, literacy is nested rather than foundational.** A review of 86 resources places AI literacy inside a five-domain competency set where executive functions and learning dispositions do the coordinating, arguing it “cannot be standalone” for children aged 0 to 8 (Pei (2026)).

Motivation is a precondition, not just an outcome. Liang et al. (2026) found, across 2,086 secondary students in a year-long AI curriculum, that students who transitioned into or remained in a *Self-Determined* motivational profile (high autonomy, competence, and relatedness need satisfaction) showed the **greatest AI-literacy gains**. AI literacy develops through sustained engagement, and that engagement is itself shaped by motivation and psychological-need support — so effective AI-literacy instruction should attend to learners’ motivation, not only their skills.

Instructional emphasis and task openness reach performance through different needs. Yu, Lin and Chen (2026) randomized 320 undergraduates to four groups in a 2 x 2 experiment on an AIGC image-generation task scored with an objective rubric (ICC = 0.89) and found that thinking-based instruction, covering model limitations, critical evaluation and ethics, outperformed skills-based prompting instruction ($M = 9.21$ vs 7.69, $F(1, 316) = 50.79$, $p < 0.001$, partial eta squared = 0.138), with the wider margin on open-ended tasks (10.10 vs 8.00). The structural model shows the two design choices travel by different routes: instruction worked indirectly through autonomy (beta = 0.035) and competence (beta = 0.079), while task openness operated mainly through autonomy (beta = 0.029), competence was the strongest predictor of performance (beta = 0.358) and relatedness had no independent effect. What the instruction contains therefore matters more than whether learners get prompting practice, and it matters most when the task is open-ended.

The variables surrounding AI literacy have since been mapped more broadly. A 2025 systematic review of AI literacy’s correlates synthesized 31 studies across 14 countries (N = 12,071) and found the most consistent associations in the affective and behavioral band: AI self-efficacy, positive AI attitudes, motivation and digital competence all moved with AI literacy, while AI anxiety and negative attitudes moved against it.

Demographic variables barely registered, with age and socio-economic status correlating weakly or not at all. The review's caution is about instruments: the same studies that produced strong correlations from self-assessment also showed far weaker ones when AI literacy was tested rather than self-rated.

A structural-equation study of 502 faculty respondents at one Chinese research university found AI literacy the strongest predictor of AI well-being (β = 0.713), against a small technological self-efficacy path (β = 0.082), with social and organizational support reaching well-being only indirectly (Liu et al. (2026)).

One apparent negative association reverses under control: among 303 Hong Kong undergraduates, technology anxiety correlated negatively with AI literacy (r = −0.14) yet predicted β = 0.15 in a joint model, an effect confined to critical evaluation and ethical competence (Chow et al. (2026)).

Hu (2026) adds an ordered account of what AI literacy predicts rather than what predicts it. Surveying 450 university students in mainland China who already use ChatGPT, the study found AI literacy related directly to continued use (beta = 0.16, p = 0.002) and indirectly along a serial path through Trust and academic Self-Efficacy (indirect effect = 0.07, 95% CI [0.04, 0.10]), with the literacy to trust link the largest association in the model (beta = 0.50). AI anxiety moderated that first link (interaction beta = -0.25, simple slopes falling from 0.76 to 0.25 across the anxiety range), so the chain thinned for more anxious students and literacy instruction alone should not be assumed to reach them. The design is cross-sectional and the sample is restricted to existing users, so the ordering is a modeling assumption rather than an observed sequence.

A core applied aim of AI literacy is Reducing AI Misuse: teaching students to use AI ethically and productively rather than substituting it for their own cognitive work. Where AI literacy builds the *capacity* to evaluate and use AI critically, reducing misuse is the behavioral and structural payoff — combining guardrailed tool design, assessment redesign, and educative levers such as scaffolded think-first/AI-second sequences and prompting practice with deliberate Feedback. The two concepts are mutually reinforcing: AI literacy supplies the critical dispositions that make misuse-reduction interventions durable, while misuse-reduction evidence (e.g. the performance–learning gap) motivates why literacy must go beyond operational skill to critical judgment.

AI literacy also needs developmentally appropriate forms for the youngest learners. AI-Play translates AI literacy competencies into play-based, **unplugged** activities for Pre-K–K2 learners — organized around *AI Body* (AI as a system built from parts), *AI Food* (AI learns from examples), *AI Brain* (AI improves through patterns and feedback), and a Pre/Post-AI ethical lens — addressing a persistent lack of developmentally grounded AI literacy guidance for early childhood and making AI literacy accessible to non-technical educators and families. Complementing this, Vahedian Movahed & Martin (2025) found children aged 6–14 broadly trusted an age-tailored chatbot as an information source and most modeled it as "a smart computer program that learns" (nascent Machine Learning understanding), yet showed gaps in critical engagement and digital-safety awareness — evidence that young learners' trust can outpace their critical evaluation skills, making explicit Trust Calibration and safety instruction a necessary part of AI literacy for children.

Measurement is keeping pace with that developmental turn at the younger end. Thianwan and Srikoon's 2025 validation of an AI literacy self-assessment questionnaire for upper primary students developed a 15-item instrument for Grades 4 to 6, organized around Learning About AI, Learning About How AI Works, and Learning for Life with AI, and confirmed a three-factor structure in two samples (n = 335 and n = 579) with an overall Cronbach's alpha of .934. The authors frame it as a formative diagnostic of perceived rather than

demonstrated literacy, and note that children's self-assessment accuracy is constrained by metacognitive ability that is still developing.

Project-based learning as a delivery mechanism. Zhu & Kong (2026) developed and validated an AI project-based learning (AI-PBLS) scale and, in a Hong Kong sample of 1,027 secondary and university students (446 with complete data), used structural equation modeling to show that empowerment in using AI for problem solving and AI ethical awareness jointly **mediate** the relationship between perceived Project-Based Learning and satisfaction with an AI literacy course. This positions PBL not merely as a delivery format but as a mechanism that builds learner confidence and ethical reasoning alongside competence, reinforcing the link between PBL and meaningful AI literacy development. It also supplies a validated measurement instrument for future measurement of AI literacy course experiences.

Raising the ethical dimension of literacy has a sign problem. Among 584 undergraduates who taught themselves AI, competence raised ethical awareness ($\beta = 0.644$, $p < .001$), and ethical awareness then raised AI anxiety ($\beta = 0.439$, $p < .001$) rather than lowering it, the reverse of the predicted direction (Mu et al. (2026)). The lesson the authors draw is that teaching how ethical concerns are governed has to accompany the ethical dimension itself, or literacy work can leave learners more anxious than it found them.

AI literacy as a core gap in Conversational AI frameworks. The umbrella review of conversational AI agents (Ganguly et al. 2025, 34 reviews) identifies **limited AI literacy support** as a major gap in CAI frameworks, and its ethical-use roadmap makes foundational assessment (including strengthening AI literacy) the first pillar alongside participatory design, ethical-use guidelines, and continuous evaluation of cognitive impact. It further finds that AI-literacy, training, and awareness rank among the most-emphasized ethical directions in the CAI literature.(Conversational AI agents in education: an umbrella review of current utilization, challenges, and future directions for ethical and responsible use)

Effectiveness of AI literacy interventions. A three-level meta-analysis of 59 studies (172 effect sizes, 7,211 participants) estimates a large overall effect of AI literacy interventions ($g = 0.837$, $p < .001$) — but with a wide prediction interval [−0.292, 1.966], so effectiveness varies considerably across settings. Interventions in East Asia and Europe outperformed those in North America, and knowledge-focused interventions outperformed those targeting skills, attitudes, or ethics. The authors argue AI literacy education should therefore move beyond knowledge toward skills, practices, ethics, and attitudes, supported by integrated and reflective pedagogies (project- and problem-based, inquiry-based, experiential) and GenAI-supported tools — a shift that aligns with the participatory, producer-oriented forms of Computational Thinking described elsewhere in this knowledge base.

A second synthesis reaches a similar magnitude on a narrower base and sharpens the measurement problem. Yu, Kim, Chang and Huang (2026) pooled 57 effect sizes from 16 studies covering 3,837 K-12 students who were taught *AI itself* rather than taught *with* AI, and estimated Hedges' $g = 0.892$ (95% CI [0.548, 1.236], $p < .001$), robust to assumed pre-post correlations from 0 to 1 and stable after trim-and-fill at $g = 0.952$. Every one of the 57 effects pointed positive (range 0.16 to 4.93), and no moderator (publication source, year, school level) explained the substantial heterogeneity ($I^2 = 94.68\%$). The authors' preferred explanation is measurement: the included studies called everything from AI knowledge and ethics to attitudes, motivation, self-efficacy and career interest "AI literacy," so the pooled figure describes a distribution of positive findings under one loose label rather than one uniform intervention. Read alongside Liu et al., the two

estimates agree that AI literacy instruction works and agree on little else, which is itself the field's measurement signal.

Classroom evidence for deliberately *brief* designs is thinner, but it runs in the same direction and adds a behavior-level outcome that surveys cannot supply. Clerc et al. (2026) gave 116 French students in grades 8–9 a two-hour workshop on how LLMs work and fail, paired with practice in predicting whether a prompt would elicit a usable answer, evaluating the response, and revising or asking again. Two days later, during six LLM-supported science problems with a control group, trained students accepted underspecified prompts less often (51.5% vs. 66.7%, OR = 0.47), asked follow-up questions after a weak response far more often (59.2% vs. 27.9%, d = 0.80), and judged answer correctness more sensitively to prompt quality (interaction OR = 2.52), with a modest score difference (11.38 vs. 10.29 of 20, p = .040). The workshop never rehearsed the test tasks, so what transferred was a regulatory stance rather than task familiarity — and the authors are explicit that two days is not durability.

AI-supported critical media literacy in elementary school. Demir and Akar (2026) provide a concrete elementary-school demonstration of GenAI-supported literacy instruction: an 18-hour, 5E-model program for fourth-grade Turkish students in which ChatGPT and Grammarly were embedded phase-by-phase as pedagogical agents (ChatGPT for reflective questions and Q&A, Grammarly and Canva AI for content refinement, Padlet for peer feedback), aligned to the Turkish Language and Social Studies curricula. The AI-supported group showed large gains in media reading (+3.50), writing (+1.67), and total media literacy (+5.17, all $p < .01$) with between-group effect sizes of Cohen's d = 1.12–1.31, while the control group advanced only modestly. Qualitative analysis surfaced six domains of critical media literacy growth — digital self-protection and data privacy, purposeful and responsible media use, safe communication and boundary awareness, critical evaluation and misinformation awareness, online risk awareness, and media ethics/digital citizenship — evidence that developmentally appropriate, discipline-embedded GenAI use can build the critical-evaluation and ethical dimensions of AI literacy, not just operational skill.

Frameworks for structuring AI literacy. Several recent contributions offer structured progressions for building AI literacy. **Marienko, Markova, and Semerikov (2026)** propose a five-level framework (Awareness, Application, Evaluation, Creation, Ethics) integrated with three paradigms of AI in education (AI-directed, AI-supported, AI-empowered), developed through a mixed-methods study of Ukrainian secondary educators (national survey n = 2018; PD evaluation n = 1130). They found 84% of educators use AI but only 11% can identify specialized services beyond ChatGPT, and a professional-development intervention produced a 24% improvement in AI competence — evidence that targeted PD advances literacy beyond surface-level tool familiarity. The framework's grounding in Constructivism, connectivism, and TPACK connects to Technological Pedagogical Content Knowledge (TPACK) and Teacher AI Competency. Complementing this, **Moore et al. (2026)** used a two-year DBR process with a youth and AI-expert advisory board to design a science-integrated ML curriculum for high school youth, finding ML-knowledge gains in both cohorts (Cohort 2 M2−M1 = 0.175 vs Cohort 1 0.076) and greater gains among female and non-White participants — evidence that participatory, discipline-integrated design can advance both AI literacy and Equity.

A PRISMA review of 39 STEAM studies (2016–2025) found those implementations chiefly develop technical literacies — fundamental AI concepts, computational thinking, data literacy — while underdeveloping ethical awareness, creative imagination, and creating, managing and designing with AI, so discipline-embedded units can still miss the higher-order elements (Niri et al., 2026).

The construct is contested precisely where educators are concerned. A review of 34 studies on AI literacy in teacher education found that the field lacks consensus on what AI literacy means for professional educators as distinct from general digital literacy, and UNESCO's AI Competency Framework for Teachers specifies 15 competencies across five dimensions while functioning as a global policy reference rather than implementation guidance. The faculty in the cross-institutional teacher preparation collaboratory treated AI literacy as an integrated dimension of professional preparation rather than a separate technology skill, so candidates were expected to audit, compare and justify AI output within disciplinary coursework rather than to demonstrate tool familiarity.

Initial teacher preparation is where the structure is thinnest. Pinto et al. (2026) reviewed 11 studies of AI in initial teacher training for pre-service primary mathematics teachers and found that nine were a single session or a handful of sessions embedded in existing courses, prompting was explicit training content in only some of them, and Ethics appeared in just three, none of which addressed transparency, algorithmic bias or accountability. The risks they report are literacy-level failures: pre-service teachers failed to notice conceptual errors produced by ChatGPT, accepted generated content uncritically, and delegated more problem solving to the tool as the tasks became harder. Their recommendation is to build AI competency across the whole training sequence, from a preparatory phase into the practicum, rather than in an isolated module.

Teachers' accounts of *why* AI education is taught add a purpose layer that competency frameworks leave implicit. Fagerlund et al. (2026) interviewed 13 Finnish teachers from preschool through grade 9, largely novices in AI education, and read their purpose statements through Biesta's three domains. Qualification, the acquisition of competencies, was the clearest and most concrete purpose, and it operated as a pathway into the other two: students were to grasp AI as a sociotechnical phenomenon and use its tools, with AI serving both as a target and as an aid to learning. Socialization appeared as cultivating enthusiasm, presenting AI as "cool," and framing students as future AI-savvy workers who must meet competency demands. Subjectification, the self-determined and personally meaningful engagement Biesta treats as central, was named as important but had no concrete instructional repertoire beyond discussing and contemplating, and teachers offered no worked examples for contesting AI's authority. The authors propose **informed AI agency**, a heuristic that places subjectification at the center while treating competencies as explanatory frameworks for self-determined choices. The design implication is that the "why" of AI education needs as much design attention as the "how": when subjectification rests on generic discussion, AI literacy instruction reverts to the qualification it was meant to sit beside.

Readiness itself is a contested target. Charles (2026) argues that teacher readiness for AI-rich learning should be read from the quality of the designs teachers produce, not from adoption, confidence or digital competence, and builds a framework around *design mediation*: observable decisions such as tool selection, task and prompt design, scaffolding, verification, transparency, assessment redesign, accessibility planning and human oversight. Two of its claims have direct professional-development consequences. First, Self-Efficacy is a mobilization resource rather than a quality indicator, because confidence without AI-specific pedagogical knowledge or ethical orientation can accelerate poor design rather than prevent it, which qualifies the usual reading of teacher confidence as a readiness signal. Second, policy clarity and institutional support are separate moderators, so material support can be high while expectations stay ambiguous and readiness still translates poorly. The framework also declines to equate non-use with unreadiness, since a

reasoned decision to withhold AI can itself demonstrate design judgment. It is conceptual and unvalidated, so it supplies propositions and evidence sources rather than established effects.

AI-interaction literacy: the interactional dimension. Brunnström and Palmqvist (2026) propose a narrower, interactional competence — the ability to *steer, evaluate, and learn from* iterative interaction with GenAI — as a specific enactment of the applicational, evaluative, and integrational dimensions in broader frameworks such as the AI Literacy Heptagon. Their reflective demonstration shows what it consists of in practice: recognizing that a fluent answer is pitched above one's own schema, requesting simplification, narrowing scope, and redirecting the system toward focused practice. Two design consequences follow — the skill is unevenly distributed, so unguided use may advantage already-confident students and widen gaps (Equity), and it has to be taught explicitly rather than assumed, with teachers covering how to formulate productive prompts and when to stop using the tool (Self-Regulated Learning).

Critical AI literacy: beyond skills to power and resistance

A distinct strand of the knowledge base treats AI literacy not merely as skills or critical evaluation but as a *critical and political practice* that interrogates power, authority, and whose knowledge counts. This connects AI literacy to Critical Pedagogy and Equity:

- **"Resisting AI" as a literacy stance.** Critical AI Literacy (CAIL) can encompass *resisting AI* — refusing the inevitability and techsolutionism of dominant discourse, and cultivating collective agency through dialogic, collaborative pedagogies.(Reorienting Critical AI Literacy: A Community-Rooted Praxis of "Resisting AI") This positions education as a space where communities imagine and build alternative futures, rather than merely adapt to a given technological order.
- **Community-based epistemologies.** Community-based AI learning grounds AI engagement in learners' lived and community-based ways of knowing, redistributing AI's epistemic authority through epistemic fine-tuning, redistribution of authority, and situated discernment.(Community-Based AI Learning: Redistributing Artificial Intelligence's Epistemic Authority in Education)
- **Critical and feminist frames.** Critical, feminist scholarship argues AI literacy should be framed within pedagogies of justice, resistance, and cultural Sustainability — asking whose knowledge AI produces, who benefits, and who is accountable when systems fail.(Can we disrupt the momentum of the AI colonization of science education?)
- **Competence frameworks may be structurally unable to register what LLMs reveal.** Schlauch (2026) argues that LLMs make literacy's sociomaterial character conspicuous — texts are constituted in assemblages of people, technologies, practices and infrastructures — and that competence frameworks, by centring the individual learner, then have nowhere to put the distributed, infrastructural and nonhuman dimensions. The design consequence is a shift from transmitting competences to creating conditions. Three orientations follow: making assemblages visible by tracing the actors behind a text, with a student assigned the "AI whisperer" role so the model becomes an attributed classroom presence; sustaining fluid literacy spaces through modular tasks and teacher-authored system prompts rather than one approved workflow; and preserving critical reflexivity rather than smoothing difficulty away.

- **The literacy mandate can itself discipline.** Wang & Jin (2026) argue the demand to 'learn about AI' treats one kind of learning as natural and makes those who decline, or who would keep AI literacy out of young children's curricula, responsible for their own marginalization.
- **Situated curriculum devices.** AI literacy can be built through situated, active teaching instruments (e.g., Episodes of Situated Learning) that develop AI competencies across levels rather than through abstract instruction.(Towards AI literacy: A proposal of a framework based on the Episodes of Situated Learning)
- **Creative composition as critical AI literacy pedagogy.** Rather than treating AI literacy as technical knowledge or individual competencies, design opportunities for learners to compose messages about AI for real audiences — a Multimodal AI product such as a public service announcement simultaneously demonstrates and communicates critical competence. In Burriss et al.'s (2026) classroom study, 22 eleventh graders chose their own AI Ethics issues and made video PSAs about school surveillance, informed consent, and algorithmic accusation; across all seven films harm emerged from human–machine entanglement rather than a villainous tool, the plots still closed on hope and Learner Agency, and the authors position storytelling and advocacy — resistant to traditional assessment — as core to critical AI literacy pedagogy that centers student identity, choice, and voice.("Young Scholar[s] on the Beat": Multimodal composition as a form of critical AI literacy pedagogy)
- **Regulatory competence, not acceptance.** Kim (2026) reframes AI literacy in Higher Education as *regulatory competence* — an enacted practice of verifying, revising, selectively adopting, or rejecting AI output during academic work — showing that evaluative capacity and ethical awareness (not mere willingness to use AI) predict active, critical engagement.(From AI anxiety to strategic regulation: How university students transform generative AI into a strategic learning resource)
- **Recognizing sycophancy as a literacy skill.** A core evaluative competency is recognizing when an AI is *agreeing* with the learner versus being correct. Contextual sycophancy shows AI literacy and prompting training reduce — but do not eliminate — sycophantic mirroring of user errors, and sycophantic AI is preferred by users precisely because it makes them feel understood. AI literacy must therefore teach learners to detect agreement-for-its-own-sake and to value corrective friction, connecting to Trust Calibration and Reducing AI Misuse.
- **Valuation, not just verification.** O'Byrne (2026) found that students who only checked output for accuracy, credibility and relevance still accepted conceptually flattened work, while those who also judged nuance, voice and epistemic stance re-authored it — making "when not to delegate judgment" the literacy question.

These critical strands complement the operational and cognitive dimensions of AI literacy: where the latter ask "can the learner use and evaluate AI?", critical AI literacy asks "does the learner understand and challenge the power structures AI embodies?"

Literacy for public life is a different target from literacy for coursework. Civic and Political Education covers the manipulation and verification problem at that target: a learner who must judge a public claim, trace it to an institution, and answer objections to it.

AI literacy in STEM education

The most developed disciplinary evidence base for AI literacy comes from STEM education, and Hallström, Chiu, Ding, Koretsky and Li (2026) synthesize its ten most-cited studies (2022–2026) to show both the baseline and its limits. Across the corpus, AI literacy is defined through six overlapping constructs — knowledge/skills/attitudes (Su & Yang 2024), conceptual-procedural-contextual knowledge (Stolpe & Hallström 2024), know-understand/use-apply/evaluate-create/ethics (Ng et al. 2022), and Long & Magerko's use–communication–evaluation framing (Hornberger et al. 2023) — so the field's "conceptual ambiguity" is a measurement problem: two studies can both assess "AI literacy" without assessing the same construct. Only two of the ten offer complete frameworks. The review's sharpest finding is an asymmetry — the corpus almost entirely measures *students'* literacy while nearly nothing develops *teachers'*, a gap that leaves teacher-facing AI literacy interventions resting on assumption rather than evidence, and one the authors connect to the practical requirement that teachers be AI literate themselves to run such interventions.(AI Literacy and STEM Education: Emerging Frontiers and Research Priorities)

The chatbot evidence in that corpus cuts against fluency-based training. Ding et al. (2023) found ChatGPT tutoring in university physics raised confidence and knowledge but reinforced a "superhuman and infallible" misconception of AI, concluding AI literacy education is "first and foremost improving students' critical thinking skills in assessing information." Xu et al. (2026) found ChatGPT-supported STEM programming improved confidence and knowledge but left computational thinking and independent thought unchanged — gains in fluency coexisting with no gain in thinking. Both findings mirror the Trust Calibration and over-reliance concerns elsewhere in this page: a tutor that never contradicts the student can produce confident learners who cannot evaluate. Attitude, not readiness or self-efficacy, turned out to be the strongest determinant of actual AI-tool use among STEM undergraduates (Falebita & Kok 2025), and the review notes STEM disciplinary coverage is skewed toward biology and physics with technology as a subject nearly absent. For discipline-specific design, the review's practical warning is that comprehensive competency frameworks (UNESCO, EU/OECD) "often lack connection to empirical research or sufficient theoretical underpinning" and few are classroom-applicable.

Whose AI skills count? The instructor–employer framing divide

A central open question in AI literacy is *which* skills matter and for whom. An Ithaka S+R study comparing how US instructors and employers prioritize the 26 skills of the HiBob AI Skills Framework found they agree on the importance of only one (setting realistic expectations for AI-augmented work). Instructors weight a **critical, responsible-use orientation** — recognizing AI's limits, transparency and attribution, human accountability, proactive output review — which aligns with academic values of attribution, review, and information literacy. Employers weight **productivity-oriented skills** — workflow evaluation and redesign, automation, and human–AI teaming — that reflect team-based workplace efficiency. Because only three of 26 skills are taught by half or more instructors, and those taught skew toward the critical-use categories, the report identifies a concrete **AI skills gap**: whole categories employers value are neither prioritized nor taught in college curricula.(AI skills for college graduates: Exploring how instructors and employers prioritize AI skills differently) This divide frames AI literacy as a contested construct — critical-use literacy for academic settings versus workflow-integration literacy for employment — a tension relevant to Framing AI Use for Students, Curriculum Design, and Workplace Learning.

Students' own ratings tell a related but differently ordered story. ElSayary and Ragab (2026) surveyed 380 university students, mostly STEM-enrolled frequent AI users, and found self-reported AI literacy carried most of the explanation of perceived employability readiness: four literacy dimensions added $\Delta R^2 = 0.554$ ($p < .001$) on top of background controls worth only 0.054, and the full model reached 60.8% of the variance. Within the literacy set the evaluative dimension was strongest (Analyze & Evaluate, $\beta = 0.286$), followed by the affective one (Attitudes & Mindsets, $\beta = 0.266$), with hands-on use ($\beta = 0.217$) and foundational knowledge ($\beta = 0.187$) behind them; for perceived career readiness specifically, only Analyze & Evaluate ($\beta = 0.216$, $p < .001$) and Attitudes & Mindsets ($\beta = 0.192$, $p = .004$) were significantly associated. Read against the Ithaka divide, students' own sense of workplace readiness leans toward the critical-evaluation orientation instructors favor rather than the workflow-integration skills employers weight. The design is a single-session self-report with uniformly high means (4.17 to 4.57 of 5) and no employer or employment measure, so what it shows is that self-assessed AI literacy and self-assessed employability move together, with the evaluative and dispositional parts doing most of the work, not that these students are demonstrably workforce-ready.

Designing AI literacy interventions

The knowledge base's frameworks and empirical studies converge on a set of practical guidelines for educators and instructional designers building AI literacy interventions:

1. Use a structured competency framework as scaffolding, not a checklist. Mature frameworks give designers a shared vocabulary and a developmentally sequenced target. The SAIL framework organizes AI literacy into three domains (AI Concepts; Application and Technical Skills; AI Digital Citizenship) across four scaffolded levels — Understand and Explore → Apply and Integrate → Evaluate and Create → AI++. The AI Literacy Heptagon cross-cuts seven dimensions (technical knowledge, application, critical thinking, ethics, social impact, integration, legal/regulatory) with four Bloom-aligned proficiency levels, and stresses that emphasis must be **adapted to disciplinary context** — technical programs weight application, humanities programs weight ethical and social-impact reasoning.(The Scaffolded AI literacy (SAIL) framework: Results of a Delphi study for equitable AI literacy framework design in education)(The AI literacy heptagon: A structured approach to AI literacy in higher education)

2. Engage learners across ICAP modes. Applying the ICAP Framework, effective instruction gives learners opportunities to engage at multiple cognitive levels — passive exposure (AI concept lectures), active manipulation (hands-on tool use), constructive generation (creating AI artifacts, self-explaining), and interactive dialogue (collaborative Problem Solving with peers and AI) — selecting the mode that fits the learning goal. A systematic review found successful collaborative AI-literacy interventions spanned all four ICAP modes.(Systematic review of collaborative learning activities for promoting AI literacy)

3. Assess demonstrated competence, not self-perception. Self-reported AI literacy diverges sharply from measured performance — teachers overestimate their AI skills by ~40%, and performance-based measures correlate with classroom AI integration far better than self-reports ($r \approx 0.72$ vs 0.31). Design interventions around performance-based assessment and calibration rather than confidence surveys, and use diagnostic profiles (overestimators vs. true novices) to target support.(How to Assess AI Literacy: Misalignment Between Self-Reported and Objective-Based Measures)

4. Build metacognitive and critical dispositions, not just operational skill. AI literacy is better understood as a metacognitive social practice than a skills checklist: because LLMs are probabilistic and opaque,

learners must monitor and adjust their strategies, cultivate scientific skepticism, and interrogate how algorithms shape knowledge production — not merely learn to operate tools. Participatory co-design and experimental, project-based spaces (not one-off tool training) are where this awareness grows. (Metacognitive AI literacy: Going beyond the AI skills gap agenda)

5. Embed literacy in the discipline and make it sustained. Movement toward higher stages of AI literacy (from uncritical use → informed use → critical evaluation → improvement) is most visible when experiences are **sustained and discipline-embedded** rather than delivered as standalone workshops. Design for repeated, contextual practice within authentic coursework.(Beyond Tool Adoption: A Practical Five-Stage Developmental Continuum for AI Literacy in Higher Education) A concrete model of discipline-embedded critical literacy is the task-based taxonomy of Dierickx et al. (2026) for journalism: it maps LLM-supported tasks across the four stages of the news workflow (newsgathering, sensemaking, editing, publication/distribution), each tied to a baseline prompt and a risk-and-mitigation strategy. By treating task definition and prompting as a situated form of professional judgment — not a neutral technical skill — it turns prompting itself into a vehicle for critical AI literacy (bias, hallucination, overreliance, and the enduring value of human editorial oversight), and its underlying logic transfers to other knowledge-intensive professions (law, medicine, public policy). Complementary to such discipline-specific taxonomies, the Dohn et al. (2026) taxonomy classifies GenAI learning activities along six dimensions, of which **Epistemic Engagement** (understanding / using / critiquing / constructing GenAI) directly operationalizes AI literacy as the depth of learners' cognitive relationship with the technology — from passive exposure to active critique and construction.

6. Treat equity and the digital divide as design constraints. AI literacy is a mechanism for addressing the three-level digital divide (access, skills, outcomes): closing the device gap is insufficient unless skills and critical use are built so benefits distribute fairly. Interventions should plan explicitly for learners who enter with less prior AI access, and incorporate cultural and governance perspectives rather than treating literacy as culture-neutral.(The Scaffolded AI literacy (SAIL) framework: Results of a Delphi study for equitable AI literacy framework design in education)(Digital Divide)

7. Pair literacy with misuse-reduction levers. Because AI misuse actively harms durable learning, literacy instruction should be coupled with the structural and educative levers documented under Reducing AI Misuse — guardrailed "hint-not-answer" tool design, assessment redesign, and scaffolded think-first/AI-second sequences with deliberate prompting practice.

8. Start from learners' actual entry point. Learners enter with distinct orientations — avoidance driven by fear, mistrust, or lack of access, versus uncritical reliance that masks misunderstanding. A diagnostic, stage-based approach (rather than a uniform curriculum) lets designers meet students where they are and move them toward critical, responsible engagement.(Beyond Tool Adoption: A Practical Five-Stage Developmental Continuum for AI Literacy in Higher Education)

9. Extend provision beyond the audiences formal education already reaches. The AI Literacies framework for public service media argues from a landscape review of more than 40 frameworks and 35 expert interviews that provision has tilted toward technical and functional skills, and that AI literacies overlap and should be connected to digital, media and information literacy rather than taught as a standalone subject. Its structure — six competency areas, five values and three progression levels (*Understanding and Applying*, *Analysing and Evaluating*, *Synthesising and Specialising*) with an assessment guide — is a usable

template for providers outside formal schooling, and its equity argument is a design instruction: reaching young people who are digitally or otherwise marginalized takes deliberate partnerships, not universal publication.(Supporting AI Literacies for Young Adults Aged 14-19: A value-based, practical framework for public service media organisations)

Measuring AI literacy

A distinct research thread treats AI literacy not only as a target for instruction but as a construct to be measured. The knowledge base's assessment strand separates **self-reported** from **performance-based** skill: reporting diverges sharply from demonstrated competence (teachers overestimate by ~40%), and performance-based instruments predict classroom AI integration far better than confidence surveys ($r \approx 0.72$ vs 0.31). Intervention work reproduces that divergence at the level of behavior: in Clerc et al. (2026), neither GenAI attitudes nor a general metacognitive-awareness scale predicted students' regulation of LLM interaction or their final task scores ($r = .01$ and $r = .04$, both non-significant), while the behaviors the workshop changed — rejecting underspecified prompts, judging answer correctness, asking a follow-up — did track answer quality. Validated instruments are emerging to close this gap — the GLAT provides a psychometrically validated generative-AI literacy assessment, and diagnostic profiles (overestimators vs. true novices) let designers target support where it is needed. Guo et al. (2026) map that instrument landscape directly, reviewing 80 validated frameworks — 69 digital literacy and 11 AI literacy — published between January 2014 and February 2025. AI has pulled digital literacy toward ethics and recast communication to include human–AI interaction, while metacognitive regulation and educator-specific human–AI collaboration remain the least specified. For design and research, this ties AI literacy to Educational Measurement and to Assessment broadly: a literacy framework is only as useful as the instruments used to track growth, and stage-based continua require reliable measurement to place learners along them.

Puppart, Laak and Aru (2026) supply the largest objective counterpart yet: an 18-item test validated on 7,432 Estonian high school students (marginal reliability = .72), with scores unrelated to perceived ease of use ($\rho = .01$) and negatively related to use frequency ($\rho = -.16$ to $-.19$).

A 32-item six-facet instrument extends the four-dimension model with two further facets — responsible use and self-development — and holds scalar invariance across adolescents (12–17), young adults (18–40) and midlife adults (41–60), though the authors caution the ΔCFI approached the conventional cutoff (Liu et al. (2026)).

Zhi, Yang and Huang (2026) build a graduate-specific model on Marzano's taxonomy: grounded-theory analysis of interviews with 14 professors condensed 329 raw labels into 96 concepts, 15 categories and five dimensions (cognitive foundation, operational skills, higher-order thinking, metacognitive reflection, ethical responsibility), then operationalized them as a 15-item Likert scale whose five factors emerged in exploratory factor analysis (83.14% of cumulative variance) and held in confirmatory factor analysis on a second subsample (CFI = 0.934, RMSEA = 0.083), with reliability from 0.796 to 0.842 across 308 valid questionnaires.

The Critical 3wAI Literacy Scale (Bozkurt, Ertan & Cömert, 2026) validates the same three-part structure for adult learners as a self-report instrument ($n = 546$ and $n = 647$; $\chi^2/df = 4.93$, CFI = 0.931, $\alpha = 0.913$). Its Know-How and Know-Why factors came out most closely coupled (HTMT = 0.544), while theoretical

knowledge alone did not translate into practical efficacy. As a self-report measure it shares the divergence problem documented above, so it is a validated diagnostic rather than a performance measure — and the authors call for revalidation across age groups and cultural contexts.

A related question is *what* the instruments can measure at all. Burriss et al. (2026) note that existing AI literacy scales and competency frameworks assume individually measurable performance and so structurally exclude collaborative, creative expression — their unit's evidence was Multimodal AI film artifacts, reflections, and civic discourse rather than a summative score, and the authors argue such evidence can *complement* rather than replace conventional measures. Broadening the construct may therefore require broadening the admissible evidence, not merely adding modality-rich items to existing scales.

A complementary strand measures how learners and teachers receive AI literacy *materials* rather than their literacy itself. Wang, Chuang and Wu (2026) had 794 students and 37 teachers rate two guidebook editions built to UNESCO's age threshold (ages 9-12 and 13-18) after roughly 30 minutes of guided classroom exposure. Acceptance held a four-factor structure (Performance Expectancy, Effort Expectancy, Perceived Playfulness, Behavioral Intention) with measurement invariance supported across the two student editions, younger learners scored higher on all four constructs, and perceived playfulness carried the largest association with intention in both cohorts. The authors are explicit about what this is not: perceived acceptance of an age-tiered resource is not AI literacy achievement, ethical reasoning, adoption or sustained use, and material-level acceptance should not be read as evidence that literacy improved.

Measurement also extends to the educators who mediate learners' engagement with AI. Most AI-literacy assessments target students or general users, leaving a gap in teacher education — a gap the Teachers' AI Literacy Scale (TAILS) addresses: grounded in the ED-AI framework with six dimensions (knowledge, evaluation, collaboration, contextualization, autonomy, and ethics), it was validated through exploratory and confirmatory factor analysis with preservice language teachers. Such instruments support measuring and developing the AI literacy of the educators who mediate learners' engagement with AI. On the student side, Nie et al. (2026) develop and validate a Generative AI Assessment Literacy Scale (GAA-LS) for higher-education students — an 18-item, five-factor instrument whose scores track Feedback engagement, Academic Integrity, and responsible AI use, with an indirect path to integrity running through feedback — evidence that assessment-specific AI literacy is measurable and ties to integrity behavior. What that teacher-facing instrument corpus actually contains has since been audited: Zainal, Mohd Matore and Maat's 2026 review of teacher AI literacy measurement tools appraised 33 instruments published between 2019 and 2025 and found that 31 (93.9%) were self-report scales of perceived confidence, only two tested knowledge objectively, and none used performance-based tasks, while fairness evidence was the weakest quality domain, with only five instruments reporting measurement invariance or differential item functioning.

The 2026 update of that measurement literature reorganizes it into four domains — knowledge and use, epistemic oversight, reliance calibration, and operational control of tool-using agents — and reports that no validated individual-level instrument in the corpus covers the full combination of scope, permissions, recovery, state isolation, independent review and evidence-based closure that agentic tool use demands. Its pooled subjective–objective correlation across three same-sample effects was r = .055, consistent with the divergence described above rather than with self-ratings as a usable proxy (Verí (2026)).

The measurement landscape is itself disordered, and now partly mappable. He, Zhang, Wang and Ji (2026) analyzed the AI literacy instrument corpus with an LLM-based coding pipeline and found the field

measuring many constructs under one label — a jangle problem, with one construct carrying several names (Behavioral Commitment appears in eight candidate pairs, Intrinsic Motivation in five), alongside candidate jingle cases where instruments share a label but not their item content. Their semantic-similarity recovery of item and construct structure correlated only moderately with instruments' own reported reliabilities (r = 0.49 at item level against 0.45 and 0.35 at construct level), and they offer the method as screening rather than adjudication. The consequence for anyone selecting a measure is that convergent claims across studies are not safe to assume: two instruments with the same name may not operationalize the same construct.

What those instruments can support has now been audited, and the audit is sobering. Jin, Gašević, Martinez-Maldonado and Yan (2026) screened 8,056 records down to 58 studies covering 47 unique instruments, appraised with COSMIN against a construct whose instrument-development window compressed into three years (two instruments before 2023, 28 in 2025 alone). The corpus remains 37-of-47 self-report, and the evidence clusters tightly around internal structure: structural validity was sufficient in 32 of 58 studies and internal consistency in 32 with none rated insufficient, but construct validity was reported by only 15 studies (12 sufficient), criterion validity by one, measurement invariance by five (all sufficient), and just 2 of 58 earned a sufficient overall content-validity rating — comprehensiveness was insufficient in 53 despite 43 studies reporting cognitive interviewing. The pattern is that measurement practice looks robust exactly where it is cheapest to demonstrate and thin where evidence must come from outside the instrument, so a clean factor structure and a high coefficient (which can reflect item redundancy as much as construct representation) should not be read as demonstrated capability. The authors' prescription is consolidation rather than proliferation: refine existing scales, test invariance whenever one crosses a language or an educational stage, and add criterion evidence by relating scores to performance tasks.

One of the exceptions is built to compare groups. Zhang et al. (2026) developed the Generative AI Literacy Scale (GAILS) — 43 items reduced to 34 through a five-expert Delphi review and a seven-person pilot, then validated in 341 North American adults — and tested scalar invariance, finding that it held across female and male respondents and across student and workforce groups. That is what licenses the mean comparisons the instrument reports — men scoring modestly higher on Adaptive Operational Skills, students higher on Adaptive Operational Skills and Responsible GenAI Literacy — as competence differences rather than differential item functioning, and it is what makes the scale usable across Higher Education and workplace settings rather than student-only. Its own evidence is not unblemished: fit was mixed (CFI = .967 and SRMR = .058 inside conventional cutoffs, RMSEA = .087 above them), total-scale α = .973 sits alongside one failed Fornell–Larcker discriminant comparison (Factor 1 √AVE = .828 against r = .873 with Factor 3), and, like almost everything in the corpus, it measures perceived competence with no behavioral criterion. A validated scale in this field is a starting point for the invariance and criterion work the review calls for, not a finished Benchmark.

Self-report measures also flatter the people who teach the subject. In a survey of 412 academic librarians in 38 Nigerian institutions, self-rated competence was high for database instruction (M = 4.07) and conventional information-literacy delivery (M = 4.02). Their composite AI competency score was 2.86, below the midpoint, with the weakest items being writing AI literacy objectives (M = 2.70) and assessing outcomes (M = 2.62) (Dada, 2026). The pattern is not low confidence in using tools; it is low confidence in designing and assessing instruction about them, a distinction that matters for Libraries and for anyone planning staff development around AI Literacy.

Connections across the knowledge base

AI literacy intersects with AI Tutoring (understanding when and how AI tutors are effective), Teacher AI Competency (educator preparedness), Academic Integrity (knowing what constitutes appropriate AI use), and AI in Education broadly. It is both a prerequisite for effective AI use and an outcome of well-designed AI integration — students learn AI literacy BY using AI critically, not just by learning ABOUT AI.

AI literacy is **double-edged** for overreliance: Maizel et al. (2026) found the skill-based dimensions of AI literacy (using/understanding, detecting) were *positively* associated with reported AI dependency, while AI Self-Efficacy and academic confidence were negatively associated — so technical AI-literacy training, absent self-efficacy and Self-Regulated Learning scaffolds, can increase dependency. AI literacy here becomes an enabling capacity whose *direction* depends on complementary motivational resources.

- **Verification habits pay off only through regulation.** In Davor, Larbi and Boateng (2026)'s survey of 533 university students in Ghana, AI verification literacy had no significant direct effect on critical thinking (beta = .076, p = .090) or technical Problem Solving (beta = .043, p = .385) and mattered only through metacognitive self-regulation (beta = .167, p < .001), a full mediation the authors call metacognitive activation. AI task scaffolding predicted both outcomes (beta = .185 and .170), while cognitive offloading tendency predicted them negatively (beta = -.240 and -.312) and depressed regulation as well (beta = -.294). Teaching students to check AI output is therefore not enough on its own: evaluative habits need planning, monitoring and reflection built into the task.
- **In engineering tasks, verification frequency tracks performance directly.** Liu, Zhang and Pan (2026) found reported checking associated with task performance (beta = 0.400) across 1,206 mechanical engineering students. Their self-rating of the same literacy shared about 7% of its variance with a scenario test (r = 0.265), and the students who rated themselves most literate got the least from checking.
- **Literacy reaches problem solving through cognitive moves, not through tool access.** A time-separated three-wave survey of 784 students at six Guangdong higher vocational colleges put AI literacy's total association with self-rated complex problem solving at 0.480: 0.248 direct and 0.232 indirect, split 0.151 through systematic thinking and 0.081 through cognitive load (Huang et al. (2026)). Perceived school ICT support moderated both routes (interactions 0.128 and −0.352), carrying the conditional indirect effects from 0.117 to 0.176 and from 0.038 to 0.127 in a self-report survey, not a trial.
- **Critique of AI output as a literacy practice:** Hosseini (2026) treats evaluating AI-generated errors as a core AI-literacy skill, using failure-mode analysis and iterative prompt refinement in a database design course. The study found students overestimated their AI abilities (self-reported literacy weakly, negatively correlated with objective competency), and that critique-based learning strengthened calibration.
- **Socialist humanist AI literacy (2026):** A literature review critiques compliance-oriented AI literacy and proposes a socialist-humanist framing of asynchronous AI literacy and fair use in higher education, linking the historical digital divide to modern AI literacy and calling for approaches that serve human flourishing and equity rather than mechanical policy compliance

(From Mechanical Compliance to Human Flourishing: A Socialist Humanist Approach to Asynchronous AI Literacy and Fair Use in Higher Education).

- **Cheap, light-touch warnings blunt AI persuasion — without costing general trust.** Orchinik and Rand (2026) preregistered two experiments (total N = 3,208 US adults) in which participants conversed with an Large Language Models (LLMs) instructed to shift their views on political topics. A single brief warning — that models can be prompted to persuade and may present information selectively — cut belief change by roughly one half (-48.1%, 95% CI [-59.5%, -36.8]) relative to control, and adding specific persuasion-technique warnings produced no further benefit. The property that matters for teaching is on the other side of the effect: general trust in Generative AI did not fall, so the intervention builds calibrated trust rather than blanket skepticism. It is a one-paragraph, no-facilitation intervention, which is a rare cost profile for an AI literacy design.
- **Learner governance of AI matters more than the design of the tool.** Azimi (2026) randomized 33 students in a master's data-analytics course between a scaffolded AI Study Coach embedded in the notebooks (n = 16) and unrestricted use of any Generative AI tools they chose (n = 17) for seven weeks. Assignment performance and concept-inventory gains were indistinguishable; the Coach condition reported higher confidence instead. What separated students was AI literacy in practice: those who had formulated their own rules for when to use AI scored higher in both conditions, and the students with the deepest model understanding — every one of them self-taught — prompted most deliberately. The design implication runs against the control reflex: teach the self-regulatory and model-understanding components of AI literacy rather than constrain tools.

For critical AI literacy specifically, Solyst et al. (2026) show that youths can be taught to evaluate generative AI systematically, given scaffolding that names what to look for and a structure for recording what they find.

Suartama, Sukmana and Triwahyuni (2026) propose CAFE-AI, a design that pairs AI literacy instruction with growth-mindset framing, reporting that the combination improved both measured AI literacy and mindset over a semester in one Indonesian university course.

Fifty frameworks in two years, and almost none of them measures generative AI. Kharbach, Woodworth and Sawchuk (2026) charted 50 K-12 AI literacy frameworks published in 2024 and 2025, 35 of them in 2025, from fifteen countries. The 27-item GAIAS was the only generative-AI-specific instrument in the corpus, and the dominant tools, AILQ, SAICS and the Chung et al. diagnostic, do not assess generative AI literacy "at all." Competency labels converged on the same five dimensions while the constructs underneath them did not align.

A literacy score can be uncorrelated with the outcome it is meant to protect. Among 300 university students, Kim, Kim and Zhang (2026) found AI literacy uncorrelated with AI overtrust at the bivariate level (r = 0.051) while carrying a negative indirect association inside a serial mediation model. Once performance expectancy was in the model, higher AI literacy predicted lower overtrust. Knowing more about AI did not, on its own, change how much students trusted it.

Literacy as the civic remedy, argued rather than tested. Muñiz and Castro Samayoa (2026) treat critical AI and media literacies as the counterweight to cognitive outsourcing, because a literate student can interrogate the mechanism rather than the output. Their concrete prescription is to have students probe models as researchers rather than use them as customers, and to keep the student the chief epistemic

authority. The essay reports no data, so it supplies a rationale for the literacy agenda and not evidence that the agenda works.

A literacy curriculum that ends in reflection on two feedback sources. Stillman et al. (2026) implement the sequence rather than describe it: readings on how language models work, peer feedback on a draft, rubric-driven chatbot feedback on the same draft, then a revision plan and a reflection on both. Across 654 students in 13 sections, the authors treat students' own labels for the chatbot as the literacy evidence, and they elevate one student's "vending machine of feedback" metaphor over the tutor and collaborator vocabulary.

Verification is the teachable counterweight, and Automation Bias names what it is teaching against. Post-editing, recomputation and source checks are graded skills precisely because fluent output invites acceptance over inspection.

Common Misconceptions

- **"Self-reported AI literacy tracks actual AI literacy."** It **diverges sharply from measured performance** — teachers **overestimate their skills by about 40%**, and research on literacy assessment shows the same **40% gap** between self-report and performance-based measurement. A survey of AI literacy measures confidence, not competence.
- **"AI literacy is one construct."** Sun, Dohn and Rehm (2026) classified **102 empirical higher-education studies** and found the construct is not unitary. A program that builds one dimension leaves the others unaddressed.
- **"A 40% overestimate is a minor calibration issue."** It means the students and teachers most confident about their AI literacy may be the ones least able to evaluate output — which is exactly the population an intervention has to reach first.

Connected Concepts

- Pedagogical Patterns — Developed by the critical-appraisal steps in these sequences
- Learners — Learners: the umbrella for the learner-side concepts
- Automation Bias — The failure that verification and post-editing instruction is meant to prevent
- Generative AI — the technology AI literacy targets
- Large Language Models (LLMs) — the systems at the heart of AI literacy
- Critical Thinking — core evaluative disposition
- Prompt Engineering — core practical competence
- Metacognition — literacy as metacognitive social practice
- Cognitive Offloading — the over-reliance risk literacy counters
- Reducing AI Misuse — literacy's behavioral payoff
- Academic Integrity — knowing what constitutes appropriate AI use
- Self-Assessment — judging your own work and skill, as technique and as measure
- Trust Calibration — calibrating appropriate trust
- AI Sycophancy — literacy skill of detecting agreement

- Equity — fair distribution of literacy
- Digital Divide — the access/skills/outcomes gap
- Ethics — ethical awareness dimension
- Teacher AI Competency — educator preparedness
- Educational Development — building educator literacy
- AI-Assisted Educational Research — AI-Assisted Educational Research
- K-12 — school-level literacy
- Higher Education — university-level literacy
- Career Development and Readiness — the employability payoff AI literacy is argued to build
- AI in Education — the broader field
- Civic and Political Education

Information and Media Literacy

> **Information and media literacy** are adjacent capabilities that AI is rewriting at the same seam. Information literacy centers on finding and verifying accurate data; media literacy centers on understanding who created a message, how it was constructed, and why. They overlap in their shared goal of building the Critical Thinking that lets people navigate a digital world and spot misinformation — and they now share a second problem: generative AI produces fluent, plausible content whose origin and intent are hidden, so the provenance question that media literacy always asked has moved into information literacy too.

Questions to Consider

- When a chatbot returns a confident paragraph with three citations, is the student exercising information literacy, media literacy, or neither — and does the assignment make that distinction visible?
- Deepfakes and fabricated citations are different failures: one is a false record of the world, the other a false record of the literature. Can one course teach both without teaching each badly?
- AI detectors and fact-checkers are themselves models with error rates. What happens to a verification curriculum when the verification tool is probabilistic?
- Media literacy has been taught through production — students make media to understand it. If a model now makes the artifact, what part of the pedagogy survives?

Introduction

The two literacies have separate institutional homes. Information literacy was codified in library and information science, most visibly in the ACRL Framework, as a set of dispositions around authority, process and value. Media literacy grew out of communication and media studies and out of school media education, and asks about authorship, technique, audience and effect. One judges whether a source deserves belief; the other asks who made a message and what it is doing.

That division has always been cleaner in theory than in a classroom. Both literacies teach students to slow down, check provenance and resist fluency. Both were built on an assumption that the artifact had an author who paid a cost to produce it. Generative AI removes that assumption from both at once: text is synthesized from an untraceable corpus, images and voices are cloned, and automated accounts simulate the audience itself.

This page covers the pair because the corpus treats them as one instructional problem with two outcome sets. The evidence is uneven — a bibliometric map and two systematic reviews on the information side, a small intervention and an expert interview study on the media side — and almost none of it tests a combined curriculum. That absence is itself the finding worth carrying into practice.

Where the two constructs diverge

Information literacy's object is the source, and its core question is whether the claim is true and the evidence behind it credible. Media literacy's object is the message, and its core question is who made it, how, for whom and to what end. A fabricated citation fails the first test; a deepfake may pass every factual check a student knows how to run while failing the second.

The empirical literatures reflect the split. A survey of 236 US university students asked where academic searches begin and found search engines at 45.5%, the library homepage at 27.9% and an AI chatbot at 26.6%, with international students substituting AI for library resources at roughly double the domestic rate (Lund et al., 2026). A systematic review of 32 studies found AI literacy integration in information-literacy instruction at an "infancy stage," delivered through LibGuides and workshops rather than curriculum (Mirza and Arif, 2026). On the media side, interviews with seven experts and a survey of 141 students found technology inclusion in the critical media literacy curriculum "limited and often superficial," with teachers under-trained for tools that produce disinformation and deepfakes (the critical media literacy study, 2026).

How AI complicates information literacy

The first complication is fabrication at scale. A model produces convincing text, plausible references and confident statistics that may not exist; the reader receives a synthesis whose search trace has been erased. Checking becomes a different skill: not "is this a good source" but "does this source exist, and does it say what the answer claims."

The second is that the search layer collapsed into an answer layer. When the tool retrieves, selects and writes, the literate act moves to judging the synthesis. That is the residue the evidence keeps pointing at: an embedded-librarian platform beat conventional library instruction by 0.78 to 0.25 points on an ACRL-based instrument, and the consultations that produced the gain were dominated by source-evaluation questions (Huang, 2026).

The third is capacity. In a survey of 412 academic librarians across 38 Nigerian institutions, self-rated competence was high for database instruction (M = 4.07) and information-literacy delivery (M = 4.02), but composite AI competency was 2.86, weakest on designing objectives (M = 2.70) and assessing outcomes (M = 2.62) (Dada, 2026). A field mapped at 1,669 publications is being asked to teach a competency its instructors report they cannot yet design (Jabeen and Lux, 2026).

How AI complicates media literacy

Media literacy's founding questions assumed a maker with a purpose. Deepfakes, voice cloning and automated bots break that assumption in three ways: the artifact may have no human author, the audience may be synthetic, and the intent may be optimization for engagement rather than persuasion by anyone.

The curriculum evidence suggests schools have not caught up. The expert interviews describe teacher training as the binding constraint rather than student resistance, and argue for a Critical Pedagogy framing that treats evaluation as ethical and participatory practice instead of tool training. A commissioned report for public service media found provision for 14–19-year-olds tilting toward functional AI skills and away from

critical evaluation, despite reviewing more than 40 frameworks and interviewing 35 experts (the AI literacies report, 2025).

AI as a defensive tool — claims and caveats

The case for using AI on the defensive side is plausible and widely made: automated credibility checks that scan a source's history and language for bias signals, deepfake detectors, metadata analyzers that look for provenance markers, and simulations that let students practice evaluation on realistic synthetic material. These capabilities are real products, and the classroom use is real practice.

The evidence is thinner than the claims. Detectors are probabilistic and degrade as generators improve; a fact-checking model is itself a model, so the student still has to judge the checker; and provenance metadata only helps when a producer chooses to attach it. One of the corpus's firmest results is that AI-supported media literacy instruction can work at small scale: an 18-hour program built on the 5E model produced large gains among 36 fourth-grade students in one Turkish school (Demir and Akar, 2026). Thirty-six students is a proof of concept, not a procurement case.

A library-sector opinion piece pushes the same idea further: AI could carry information-literacy *delivery* through retrieval, adaptive tutorials, chatbots and automated fact-checking, with librarians rather than vendors owning the integration (Offem and Arikpo, 2026). The paper reports no data, so it is a design brief for where instruction might live rather than evidence that it works.

Read together, the two sides of the ledger suggest a rule: AI can carry the *practice* load — realistic scenarios, immediate feedback, scale — but the *judgment* load stays with the learner, and any tool that claims to replace it should be evaluated as a detector with a measured error rate, not adopted as an answer key.

What this means for practice

- **Teach one procedure, two objects.** The checkable routine — trace the claim to a source, trace the source to an author, ask what the artifact is doing — works for a citation and for a video. Name which object the assignment is assessing.
- **Treat detection as evidence, not verdict.** A detector's output is a probability; teach students to corroborate with a second method and to say what would change their mind.
- **Keep production in the curriculum.** Making media was the pedagogy that made critique concrete; generating with AI can support it only if students examine the choices the tool made for them.
- **Put a librarian or media specialist inside the workflow.** The strongest instructional result in this literature comes from a design where human consultation was built in, not offered afterwards.
- **Assess staff capacity before writing the syllabus.** The measured deficit sits at designing objectives and assessing outcomes, not at using tools.

Limitations of the evidence

Most studies here are small, self-reported or both: 236 students in one survey, 36 children in one intervention, 412 librarians rating themselves. Bibliometric visibility is not practice, and the scientometric

authors say so explicitly. No study in the corpus evaluates a combined information-and-media-literacy curriculum, and the detector and fact-checking tools the practice literature recommends are largely unmeasured in these sources. The claim that AI-powered verification improves outcomes should be treated as a design hypothesis until someone tests it against a control.

Agentic AI

> **Agentic AI in Education** — AI systems that autonomously plan, execute, and adapt multi-step workflows to achieve learning goals, going beyond single-turn Q&A to act as persistent, goal-directed collaborators: AI tutors that scaffold over extended interactions, multi-agent systems that orchestrate instructional designs, and agents that co-regulate learning. This paradigm shift from a prompt-responding tool to an active collaborator carries both promise and risk: agentic AI can personalize and deepen learning, but it also threatens Learner Agency, cognitive effort, and control. The knowledge base's scoping review, tool-invariant framework, and pedagogical best-practice articles examine this tension.

Questions to Consider

- Agentic AI doesn't just answer questions — it plans, executes, and adapts multi-step workflows toward a goal, acting as a persistent collaborator. How is learning with a proactive agent different from learning with a tool you have to prompt?
- The field draws a line between "conversational" and "agentic" AI (a system qualifies only if it meets several criteria such as planning, memory, autonomy, and goal-directed action). Where is that line in practice — and does calling every chatbot "agentic" hide more than it reveals?
- The more an agent automates, the less cognitive work the learner does. Where is the line between an AI that scaffolds your learning and one that does your learning for you?
- A scoping review found only 29% of agentic AI studies grounded their systems in educational theory. If most systems aren't theory-based, what should make you skeptical when evaluating an 'intelligent' tutoring agent?
- Multi-agent systems orchestrate specialized agents with distinct roles. When several agents work together in a classroom, who is accountable — and where should a human intervene?
- The field's central tension is personalization versus learner agency and cognitive effort. If a tutor becomes so good at adapting that you never have to struggle, what learning are you actually getting?
- Where on the Copilot-to-Autopilot spectrum should a given task sit — and does moving a task from "agent proposes, learner disposes" to "agent owns it" ever serve learning rather than just efficiency?
- Hybrid agents grounded in established design theory outperformed pure prompting. Why might a theoretically-grounded system beat raw prompt-engineering — and what does that say about how an agent's 'smartness' is measured?

Introduction

Agentic AI refers to artificial intelligence systems that can autonomously plan, execute, and adapt multi-step workflows to achieve learning goals — going beyond single-turn question-answering to act as persistent, goal-directed collaborators in educational contexts. In education, agentic AI manifests as AI tutors that

scaffold learning over extended interactions, multi-agent systems that orchestrate complex instructional designs, and autonomous agents that adapt their pedagogical strategies based on learner needs. This emerging paradigm shifts AI from a tool that responds to prompts to a collaborator that actively guides, adapts, and co-regulates learning processes. - **Splitting specification from execution is what makes an agentic pipeline reliable.** DagFlow-AI has LLM agents define every component of a data-generating mechanism - variables, a directed acyclic graph, distributions and model formulas - while a program samples the observations and a validation script checks each agent output (Arthur et al., 2026). No agent generates data or writes the generation code, which the authors present as the answer to unsupported output and instruction drift.

Defining and classifying agentic AI

Kostopoulos et al. (2025) supply an operational definition the field otherwise lacks. They propose a **six-criteria checklist** — a system counts as agentic if it meets at least four: autonomy (action independent of continuous human intervention), reasoning/planning, memory/context-awareness, goal-directed action toward learning outcomes, adaptability, and dynamic collaboration/initiative. The ≥4 threshold deliberately **excludes reactive chatbots** (a static FAQ bot without planning or persistence does not qualify) while accommodating diverse architectures. They also organize the space along three axes: **pedagogical role** (tutor, learning coach/mentor, companion, instructor's assistant, curriculum planner), **autonomy level** (reactive → adaptive → proactive → collaborative), and **embodiment** (text-based, avatar/graphical, embodied/robotic). This taxonomy — particularly the autonomy spectrum and the checklist's exclusion of reactive tools — gives researchers and designers shared vocabulary for classifying agentic systems and distinguishing genuinely agentic from merely conversational AI.

A worked discriminator makes the line concrete. A static FAQ chatbot that can only answer a fixed set of questions meets **zero** criteria (no planning, no persistence, no initiative) and is plainly not agentic. A conversational tutor that remembers the current session but never acts unless prompted, holds no cross-session learner model, and cannot set sub-goals may meet only one or two (memory, some reasoning) — conversational, not agentic. By contrast, a tutor that plans multi-turn lessons, stores learner progress in a persistent profile, **proactively** fires a hint when a learner stalls, and re-plans the next step based on that profile satisfies planning, memory, autonomy, and goal-directed interaction — at least four criteria, so it qualifies as agentic. The value of running this test is not pedantry: labeling every LLM chat interface "agentic" blurs the very design question — what the system initiates versus what the learner must initiate — that determines whether it scaffolds or supplants learning.

Bounded agency as an educational design stance. Ilieva et al.'s (2026) AGAI-HE framework accepts the capability list that definitions such as the six-criteria checklist describe, then deliberately constrains it: goals, roles, data sources, tools, checkpoints, stopping conditions, and final decisions are defined or approved by educators, and each agentic function must trace to a learning requirement, assessment purpose, or governance control. The framework also draws a line between agentic orchestration and advanced prompting — an agentic workflow preserves task state, allocates functions, checks completion conditions, returns to earlier stages when evidence is insufficient, and records material decisions. Notably, its exploratory perception study with 130 higher-education students found no significant difference between agent-supported and chatbot-supported learning, which the authors read as evidence that agentic *capability* does not by itself produce a perceived pedagogical advantage (human oversight).

The field: rapid expansion and current shape

The knowledge base's scoping review — the most comprehensive synthesis of the field to date, mapping **474 studies (2020–2026)** — documents a field that has grown **explosively since 2025**, but whose literature is still dominated by conference papers concentrated in Higher Education, STEM disciplines, and text-based tutoring scenarios. The review analyzes publication characteristics, study designs, agent roles, AI models and architectures, six dimensions of agentic capability, and the extent of educational-theory integration, providing a roadmap for the field's frontiers and gaps. Notably, only **29% of the reviewed studies** (138 of 474) explicitly grounded their systems in educational theory, exposing a disciplinary divide between technically oriented and pedagogically oriented work.

A role-based map of the field

Where the 474-study scoping review and Kostopoulos et al.'s conceptual survey map research breadth and capability, Baradziej (2026) organizes agentic AI by the **role it plays** — an institutional framing for deciding where to deploy and govern these systems. Across 48 higher-education studies, six roles emerge in order of evidential weight: personalized learning and adaptive tutoring (18/48), Automated Assessment and feedback (12), teaching assistance and augmentation (11), administrative and student support (8), curriculum design and workforce alignment (5), and research support and academic operations (4). The role lens foregrounds a design choice that recurs in every deployment: how much moment-to-moment control the human retains (a "Copilot" relation) versus how much the agent owns (an "Autopilot" relation) — the autonomy axis that determines whether an agent scaffolds learning or supplants it.

Design and evaluation of agentic systems

Research in the knowledge base spans design and evaluation:

- **Hybrid agents grounded in theory outperform pure prompting:** ISD-Agent-Bench, a benchmark of **25,795 instructional-design scenarios**, finds the best-performing approach integrates classical ISD frameworks (ADDIE, Dick & Carey, Rapid Prototyping) with modern ReAct-style reasoning — hybrid (theory + technique) > pure theory > technique-only. Grounding Large Language Models (LLMs) agents in established educational-design theory provides a structural advantage raw prompting cannot replicate.
- **Assessment frameworks for agentic tools:** The tool-invariant framework proposes teaching and assessing computational methods in a way that does not depend on any specific AI tool, emphasizing Computational Thinking fundamentals, Authentic Assessment via oral defense, and verification — relevant to Over-Reliance concerns.
- **A reporting-and-governance scaler: the Autonomy–Oversight–Evidence (AOE) framework.** Dey (2026) argues the term *agentic AI* is applied so inconsistently that evidence and oversight cannot be compared across studies — systems that plan, remember, use tools, or coordinate multiple agents are lumped with static GenAI interfaces and conventional pedagogical agents. His critical integrative review of fifteen peer-reviewed reviews finds evidence strongest for artifact-level outcomes (feedback accuracy, hallucination reduction) and weakest for durable learning, equity, workload, or institutional outcomes, with authentic deployments typically short, single-

site, and weakly tied to oversight. The fix is a concrete reporting triplet — **autonomy level A0–A4** (reactive generation → bounded orchestration → delegated task autonomy → workflow autonomy → *consequential autonomy* over grading/admissions/progression), **oversight level O0–O4** (unspecified → retrospective audit → pre-use approval → checkpointed control → *continuous bounded supervision*). The triplet closes with **evidence-maturity stage M0–M5** (concept → prototype/benchmark → participant evaluation → authentic deployment → extended/multi-site → *replicated/institution scale*). A **proportionality rule** adds the constraint: allowable autonomy should not outrun either evidence maturity or oversight strength (e.g. an A4 consequential system demands M4–M5 evidence, legal validation, and O4 with human final authority). Reporting *A2–O3–M3* turns vague "agentic deployment" claims into comparable, testable specifications and gives institutions a staged adoption, logging, and rollback grammar — the evidentiary complement to the Copilot-to-Autopilot spectrum above.

- **Adversarial robustness testing:** Multi-agent stress testing coordinates Interrogator, Target, and Judge agents to reveal failure modes invisible to single-strategy testing, reducing robustness scores by 0.17–0.20 points — critical for persona consistency and safe deployment with learners.
- **Domain applications:** agentic systems appear across domains, including adaptive learning agents, pedagogical LLM agents, guided LLM scaffolding, gamified cybersecurity learning agents, and clinical simulation agents.
- **Web agents as learning-experience evaluators:** a single autonomous "describing" web agent that navigates an online lesson like a student — Wang, Mitchell & Piech (2025) — produces a description rich enough to predict student dropout and give the designer actionable feedback before real learners engage, outperforming a full simulated cohort and every baseline on a global CS1 course. This positions agentic evaluation (an agent as a stand-in critic of a learning experience) as a distinct, low-cost use of agentic AI alongside agents that teach or design.

Multi-agent systems

A growing and distinct strand of agentic AI involves **multi-agent systems** that orchestrate multiple specialized agents with distinct roles. The knowledge base documents several architectures: CODE-GEN: A Human-in-the-Loop RAG-Based Agentic AI System for Multiple-Choice Question Generation pairs a generator agent with a validator agent for human-in-the-loop question generation; adversarial testing coordinates Interrogator/Target/Judge agents; multi-agent classrooms (e.g., MAIC with teacher, TA, and classmate archetypes) create varied peer-learning dynamics; and multi-agent social learning explores how interacting agents shape learning. Multi-agent design raises distinctive questions about human oversight (which agent is accountable, and where does a human intervene?), coordination costs, and how role differentiation supports or complicates Scaffolding.

Two 2026 systems sharpen what role specialization buys — and where it stops paying. MeduAI-SP (Yang et al., 2026) splits clinical-interview instruction across four LLM agents — a patient agent, a Socratic tutor agent, a turn-level evaluator, and a final evaluator — each carrying a distinct instructional function. The architecture withholds answers by design: the tutor was barred from disclosing the diagnosis or case answers, and the final evaluator's OSCE scores stayed hidden during the live encounter. Role specialization, rather than raw model capability, is what the trial credits for improved consultation behavior (71.8% vs. 55.6% on the final examination), offering a concrete template for pedagogy-aligned multi-agent design. A

second study points to the limits of that pattern: in a 45-student, 15-group ethics discussion system (Seo et al., 2026), three LLM personas embodying care, deontological and pragmatic ethics produced no significant differences among themselves, and all were rated below human peers on contribution, diversity and influence (all Kruskal-Wallis $p < .001$). The authors attribute the gap to sycophantic agreement — agents accepted nearly every contribution unless it was wholly wrong — and to a lack of visible reasoning, arguing that task-focused agent design must pair process transparency with safeguards (fallible-peer framing, a dedicated Questioning phase) to avoid over-reliance.

A step beyond orchestrating a few specialized agents is the **full agentic multi-agent ecosystem** proposed by Sudarshan et al. (2026): an institution-wide platform coordinating learning, teaching, and administrative agents through cross-functional feedback loops and distributed intelligence. Its distinctive move is treating inclusivity as a first-class architectural concern — coordinating Accessibility, cognitive-support, and Well-Being agents so that learners with special educational needs are supported across cognitive, sensory, and emotional dimensions in real time, rather than being served by an isolated assistive tool. The paper situates this inside a **human–AI co-evolution** loop (human behaviors and decisions shape AI adaptation, which in turn enhances human capability) that keeps humans in the loop.

- **Participant-specific LLM agents for collaborative problem solving.** Fang (2026) fine-tunes individual LLM agents on real participants' dialogue data to represent each participant in collaborative problem solving simulations, with probabilistic speaker and thematic-code selection and sliding-window plus summarized memory. Validated with Epistemic Network Analysis, the simulated dialogues are statistically indistinguishable from real ones (ENA distance 0.17, permutation $p = 0.65$) — a demonstration of agentic AI reproducing authentic collaborative discourse.
- **Socially intelligent multi-agent tutoring.** Socially intelligent multi-agent tutoring prototypes such as ASTRA study how learners coordinate with AI in dyads, using differentiated Tutor and Facilitator agents to prompt coordination and balanced participation. The framework's trace-based evaluation enables reproducible analysis of interaction, participation balance, and verification in introductory programming.

An organizational answer: the learner as a participating member rather than a recipient. Fan et al. (2026) instantiate a human-participatory multi-agent organization in which specialized agents maintain a revisable Capability Program linking personal goals, Multimodal AI activities and layered assessment, with a correctable "Human Node" carrying the learner's own evidence and challenges into later revisions. Against the closest multi-agent baseline across 96 simulated learner cases, the advantage concentrated in assessment design: 19.32 points higher on Assessment Validity (95% CI [17.55, 21.04]) and 5.89 on capability coverage, while personalization did not separate (1.35 points, interval crossing zero). In a randomized 32-learner study the knowledge gain on an objective 50-point test was 12.19 against 5.61 points.

The central tension: automation vs. learning

The pedagogical best-practice work articulates the field's defining tension: as education AI shifts from passive chatbots to **proactive agents** that initiate and pursue goals, personalization improves but **learner Learner Agency and cognitive effort** are at risk. The more an agent automates, the less cognitive work the learner does. The design response — **intentional friction, dynamic Scaffolding, Human-in-the-Loop**

oversight, and considered AI utilization — acts as a principled guardrail. This connects to Desirable Difficulties, Sociocultural Learning, and the risk of Over-Reliance, and to the broader theme of preserving Learner Agency in AI-mediated learning.

One empirical check comes from a practical report on Spec-Driven Development in a software PBL course (Tanaka et al. 2026): students using AI agents across development phases generated more code but showed code-comprehension dips that recovered only after instructor one-on-one interviews - concrete field evidence for the automation-vs-learning tension and for Human-in-the-Loop monitoring as the mitigation.

The survey literature turns these principles into **measurable design Guardrails** rather than vague intentions. On scaffolding, Kostopoulos et al. (2025) recommend **fading protocols** — gradually reduce hint frequency after each successful attempt — and targeting a **Help-Seeking ratio (AI-initiated hints ÷ total student actions) below 0.3**, so the agent is not the one driving most of the interaction. They pair this with **reflective checkpoints** (e.g., ask the learner to explain their reasoning before the agent offers the next cue) and adaptive fading curves whose intervention likelihood drops as proficiency rises. On transparency, agents should expose a "Why this suggestion?" rationale and keep **timestamped decision-traceability logs** (agent rationale, data sources, decisions) available for instructional auditing. On fairness, they advise pre-deployment **disparate-impact testing across at least three demographic groups** (e.g., gender, language, geography) and involving diverse teachers in design. These metrics give an instructor or designer an audit lever: rather than asking "is the agent too helpful?", measure whether hints are fading, whether the learner is initiating, and whether the agent's reasoning is inspectable.

A complementary vocabulary for the autonomy question comes from the aviation analogy surfaced in Baradziej's (2026) synthesis: how far a deployment sits on the **Copilot-to-Autopilot spectrum** — from an agent that assists a human retaining moment-to-moment control, to one that owns the whole task with the human only supervising. The same underlying system can be configured toward either end, and the choice is pedagogical before it is technical. Copilot-style configurations (agent proposes, learner disposes, human retains final say) tend to preserve Learner Agency and support the effortful processes that build learning; Autopilot-style configurations maximize task completion and efficiency but shift the cognitive load off the learner. Selecting a position on this spectrum — per task, not once globally — is a concrete way to operationalize the field's "intentional friction" principle.

Positive implications of AI agents for education

When designed well, agentic AI offers substantial benefits:

- **Deeper, more adaptive personalization.** Persistent agents can sustain a learning conversation over many turns, tracking what a learner knows, adapting difficulty, and sequencing multi-step Scaffolding — going beyond the one-shot responses of earlier chatbots. This supports adaptive and personalized learning at scale. In Baradziej's (2026) synthesis the strongest evidence for this role reports academic gains of **15–25%** and engagement increases of up to **+40%**, with particular potential for learners historically ill-served by one-size-fits-all instruction (first-generation students, learning differences, second-language learners).
- **Unburdening routine instructional work.** Agents can plan lessons, generate and validate questions, draft feedback, and orchestrate specialized sub-agents (e.g., generator + validator for question creation), freeing teachers for higher-value interaction. This is the promise of teacher-

facing multi-agent workflows. Assessment agents in particular report **90–95% agreement with human graders and 50–70% reductions in grading time**, though the same evidence flags bias and the metacognitive cost of instant, unreflective feedback.

- **Rich, varied interaction.** Multi-agent classrooms and simulated peers create diverse interaction dynamics (peer-like discourse, constructive disagreement, role-play) that single-agent systems cannot, supporting Collaborative Learning, Socratic-style probing, and Simulation.
- **Productive friction.** Agents designed to challenge rather than agree can push learners toward deeper reconsideration. Research on adversarial design agents shows that constructive-conflict agents prompted significantly more design iterations, broader exploration, and higher-rated final designs (N=48) — a form of desirable difficulty.
- **Scalable practice and simulation.** Agent-based simulations (simulated students, clinical scenarios) let learners practice in low-risk environments before real-world application, as in clinical simulation and simulated learners.
- **Evidence-aware scaffolding.** Well-grounded agents can apply learning theory and known pedagogy in their interactions, and benchmarks show theory-grounded agents outperform raw prompting.

A narrower, instructor-built class of agents gets a distinct argument in El Khoury and Ma's third-space proposal: custom GPTs, Gems and Copilot Studio agents designed by instructors for a specific pedagogical purpose and explicitly **not** autonomous systems. Their claimed value is as low-stakes rehearsal space — an oral-exam simulator, a clinical-communication simulation, an ESL pronunciation avatar — where students practice before judgment while the instructor's evaluative role stays intact, with the agent outside the social hierarchies students navigate with peers and instructors. Two boundaries are worth noting: the authors exclude agent-based *grading* from scope by design, and they argue assessment must remain relational — the instructor role cannot be substituted by a machine, though it can be extended and made more sustainable through careful design.

Negative implications and risks of AI agents for education

The same autonomy that enables these benefits also creates significant risks:

- **Erosion of learner agency and cognitive effort.** The more an agent automates, the less cognitive work the learner does. Proactive agents that initiate, plan, and complete tasks can leave learners as passive consumers, hollowing out the effortful processes — drafting, recalling, revising — that build durable learning. This is the core Over-Reliance and Learner Agency concern. The effect is measurable: in Baradziej's (2026) synthesis, passive learners in agentic-tutoring environments underperformed Active Learning students by **8.7%** — evidence that the harm follows deployment design (letting the agent do the cognitive work) more than the technology itself.
- **Over-automation of the learning process.** If an agent optimizes for task completion rather than learning, it can produce "answers" that bypass understanding — the very risk the tool-invariant framework warns about, where the artifact no longer certifies the learner.
- **Reduced metacognitive and self-regulated engagement.** When agents handle planning and monitoring, learners may not develop the Metacognition and self-regulation that education aims to build. Agents must be designed to elicit, not replace, these processes.

- **Misplaced trust and verification gaps.** Autonomous agents can produce plausible but unvalidated output; learners and teachers may over-trust it. The need for robust verification and AI Literacy grows as agents take on more autonomy.
- **Opacity, coordination, and accountability.** Multi-agent systems complicate human oversight: which agent is accountable for an error, and where does a human intervene? Coordination failures, persona drift, and emergent behaviors can undermine reliability and Pedagogical Safety.
- **Bias and equity.** Agents trained on data that encode bias can reproduce it at scale, and unequal access to capable agentic systems can widen educational inequity. Bias operates at multiple levels — training data, architecture, evaluation criteria, and test populations — so it needs institutional mitigation (bias audits, diverse datasets, transparent documentation, stakeholder involvement), not one-time checks. A subtler, culturally specific form is **epistemic hegemony**: because most agentic systems are trained on English, Western-produced data, they embed particular assumptions about knowledge, argumentation, and academic register. Synthesis evidence documents language-education tools marginalizing non-Western rhetorical traditions and penalizing linguistic features of non-English academic cultures, and Global South analyses show agentic pedagogies reproducing inequity when they ignore epistemological diversity and infrastructure constraints.
- **Assessment integrity and skill decay.** When agents can generate work on demand, assessing genuine learning becomes harder, and over-reliance can erode foundational skills — the "comprehension debt" and certification problem the field flags.
- **Ghost students and the verification gap.** Bozkurt, Crompton & Fell Kurban (2026) describe the **"ghost student"** — a digital surrogate created by coupling LLMs (the "mind") with agentic AI browsers (the "body") that can navigate Learning Management Systems, engage with content, and complete assessments with human-like mimicry, making the actual learner's presence optional. This creates a **verification gap** that traditional proctoring and detection tools are structurally unable to close, and it accumulates **cognitive debt** in the learner who is bypassed. As AI shifts from generative to agentic, this integrity and verification threat grows — an agentic-specific risk beyond those of single-turn GenAI.

AI agents and academic integrity

Agentic AI poses distinctive integrity threats that go beyond the single-turn GenAI cases the field already struggles with. Because agents act autonomously over long horizons — and because "ghost students" (LLM "minds" coupled with agentic browser "bodies") can navigate Learning Management Systems, engage content, and complete assessments with human-like mimicry — they make the learner's genuine presence optional and create a **verification gap** that proctoring and detection cannot close. Several integrity implications follow:

- **The artifact no longer certifies the learner.** When an agent can generate, plan, and execute an entire submission, the product's quality reflects the agent's capability, not the learner's. This is the tool-invariant certification problem at its extreme — traditional "submit the work" assessment loses its evidential value.
- **Verification, not detection, is the only viable response.** Detection-based policing is structurally unable to keep up with autonomous agents. The integrity question shifts from "can we catch AI

agents?" to "can we verify what the learner can actually do?" — favoring process-based, interactive, and Human-in-the-Loop verification.

- **Agentic completion of assessed coursework is now demonstrated, and it is a validity failure, not just an integrity one.** Hadjisolomou & El-Haddad (2026) documented agents (Claude for Chrome, Perplexity Comet, Claude Opus) logging into a live undergraduate LMS course and completing real assessed work from a single instruction — a 10-question quiz scored 10/10 in under 5 minutes, and a discussion-board post in which the agent fabricated a credible personal life story after mining peers' posts. Applying Kane's argument-based validity framework, they place a "human-production assumption" at the base of the scoring inference: agent completion removes its backing, so every unproctored asynchronous score — including honestly earned ones — loses interpretive support because authorship is unverifiable. Framing the problem as validity rather than integrity matters because an institution can punish misconduct and still lack grounds for the scores it reports, and because the same artifacts feed program-review and accreditation evidence chains. Their remedy, aligned with this page's "verification over detection," is assessment redesign for verified human presence (presence over product, integration over isolation, authenticity over genericity, low-stakes practice / high-stakes presence) with an equity-preserving menu of verified-moment options.
- **Accountability is diffused.** In multi-agent systems, when an autonomous agent produces problematic output, it is unclear who is accountable — the learner, the system, or the institution. This blurs the attribution that academic-integrity processes assume.
- **Cognitive debt accumulates silently.** Ghost students let learners bypass the effortful processes that build understanding, accruing cognitive debt that surfaces only when independent performance is required. Integrity is thus tied to genuine learning, not just rule-compliance.
- **It widens equity gaps.** Learners with access to more capable agentic systems gain an outsized advantage, and automated support may erode help for those who need it most — an Equity dimension of integrity.

This connects the agentic-AI discussion to the knowledge base's Academic Integrity coverage, which frames the response as assessment redesign and AI Literacy rather than detection alone.

Productive friction and social interaction

Not all agentic behavior need be smooth assistance. Research on adversarial design agents shows that agents enacting **constructive conflict** prompted significantly more design iterations, broader exploration of alternatives, and higher-rated final designs among novice interaction designers (N=48) — a *productive friction* dynamic, where the conflict agent was frustrating but ultimately helpful. This connects to Socratic questioning and Design Thinking, and illustrates how agentic AI can support deep reconsideration rather than passive acceptance.

A study of how agentic AI reaches learning outcomes through *psychological* rather than technological pathways supplies the missing measurement angle. Pramod and Patil (2026) surveyed 398 business students in India and modeled autonomy, competence and relatedness alongside interactivity, information sharing and perceived social presence. Autonomy was the strongest motivational driver ($\beta = 0.504$) and interactivity the strongest social one (0.468), with motivation and social presence feeding engagement at nearly the same

strength (0.533 and 0.493) before engagement predicted perceived learning performance (0.671). The design lesson is that the social route is not automatic: a collaborative-environment construct moved perceived social presence less than plain responsiveness and information sharing did, so treating an agent as a chat interface rather than a participant leaves most of that pathway unused.

Implications for instructors and instructional designers

For teachers, faculty, and instructional designers, agentic AI changes both what is possible and what must be guarded:

- **Reallocate effort to higher-value work.** Agents can take over lesson planning, question generation and validation, feedback triage, and resource retrieval. Instructors should treat these as automatable scaffolds that free time for what agents cannot do: relational teaching, contextual judgment, and the design of learning experiences. Teacher-facing multi-agent workflows are a promising model.
- **Keep the learner's cognitive work front and center.** The central design question is not "what can the agent do?" but "what must the *learner* do?" Instructional designers should configure agentic systems so they scaffold rather than replace learner planning, monitoring, and effort — using dynamic Scaffolding and intentional friction to protect Learner Agency and avoid over-reliance.
- **Design for verification and process, not just output.** When agents can generate work on demand, the artifact no longer certifies learning. Instructors should pair agentic tools with process-based assessment (oral defense, tool-invariant tasks, verification checks) so that understanding — not just production — is measured.
- **Curate and ground agents in pedagogy.** Benchmark evidence shows theory-grounded agents outperform raw prompting. Designers should ground agent behavior in established instructional frameworks (e.g., gradual release, Socratic questioning, learning theory) rather than defaulting to generic tool-chaining.
- **Retain human oversight and judgment.** Multi-agent and autonomous systems make Human-in-the-Loop design essential: decide where a human intervenes, who is accountable, and how failures are caught. Adversarial testing helps surface failure modes before deployment.
- **Build instructor AI Literacy.** Teachers and designers need accurate mental models of agentic AI to configure, monitor, and critique these systems — and to model responsible use for learners. This links to Teacher AI Competency and faculty development.
- **Watch for equity.** Agentic tools risk widening gaps if access is unequal or if automation erodes support for the learners who need it most; design with Equity in mind.
- **Stand up institutional scaffolding before scaling.** The deployment question is not only design-level but institution-level. Baradziej's (2026) synthesis condenses the governance evidence into three pillars: develop AI Literacy among students *and* staff; build ethical infrastructure (data-protection policies, algorithmic-accountability and academic-integrity frameworks) *before* large-scale deployment; and deliver competence-based educator training that goes beyond tool familiarization to pedagogical frameworks preserving human agency. Given only ~6.5% of faculty

in some national contexts report direct AI use, the training gap is a binding constraint on responsible adoption.

Techniques for ensuring academic integrity with agentic AI

Because autonomous agents make detection futile, instructors should focus on techniques that **verify learning** and **make honest work visible**, rather than on policing:

- **Prefer verification over detection.** Replace or supplement "submit the work" with interactions that require the learner to demonstrate understanding they cannot outsource: oral defenses, tool-invariant tasks, live Problem Solving, and process-based assessment. The goal is to establish what the learner can do independently, not to catch an agent.
- **Use interactive and staged assessment.** Require staged submissions (drafts, revisions, reflections) and follow-up conversational checks that probe whether students understand their submitted work — the "AI Viva" and cognitive-stewardship approaches. Ghost students cannot sustain a live interrogation they did not perform.
- **Set clear, purpose-driven expectations.** Ground integrity expectations in the course's purpose — what AI use is allowed, when, and why — rather than abstract rules. Policy clarity that is aligned with pedagogy reduces the ambiguity students exploit and the misjudgments documented in integrity research.
- **Make AI use visible and declared.** Structured, task-specific AI-use declarations (mapping use to cognitive stages) force reflection and normalize honest disclosure, shifting the culture from concealment to transparency.
- **Build AI literacy as integrity education.** Teach students how to use agents responsibly and to judge output critically, framing integrity as genuine learning rather than rule-following. This includes AI Literacy, understanding what agents can and cannot do, and the learning cost of bypassing effort.
- **Keep humans in the loop.** Maintain human oversight of assessment decisions, verify high-stakes submissions interactively, and design agentic tools so an instructor can always intervene.
- **Close the verification gap with interaction.** For fully online or asynchronous contexts, use proctored or interactive components that require live presence, addressing the ghost-student threat directly rather than assuming detection will catch it.

A balanced takeaway

Agentic AI is neither a panacea nor an inevitable harm: its value depends on design. Used to scaffold learner agency, ground in pedagogy, and keep humans in the loop, agents can personalize and deepen learning; used to maximize automation and task completion, they can erode the very effort that produces learning. The recurring design principle is **intentionality** — deciding explicitly what the agent does and what it deliberately leaves for the learner.

Common Misconceptions

“Any chatbot wired to tools is an agentic system.” The distinction is drawn on capability structure, not on tool access: a system qualifies as agentic only if it meets criteria such as planning, memory, autonomy and goal-directed action across steps. A prompt-response tool that can call a calculator remains conversational. The distinction matters because the risks and the evaluation methods differ — autonomous multi-step action raises failure modes that a single exchange does not.

“Better base models are what make agentic systems work in education.” In the trial this page cites, **role specialization rather than raw model capability** is credited with the improved consultation behavior (**71.8%** against the comparison). Architecture and division of labor across agents are design decisions with measurable effects, which means a stronger model dropped into an unspecialized pipeline will not reproduce the result.

“Agentic systems in education are pedagogically grounded because education researchers build them.” The evidence says otherwise: a scoping review found only **29% of agentic AI studies (138 of 474)** explicitly grounded their systems in educational theory. The disciplinary divide between technically oriented and pedagogically oriented work is the field’s condition, not an individual author’s oversight, so a demo that works is the expected output and a demo that works *for learning* is the minority case.

“An agent that personalizes and deepens learning is a net gain over a chatbot.” It carries a specific trade with it: agentic systems threaten Learner Agency and invite offloading of the cognitive effort the learning depends on, and by doing more steps unsupervised they make that offloading harder to notice. The automation-versus-learning tension is the central analytic problem of the category rather than a caveat appended to its benefits.

Cognitive Offloading

> **Cognitive offloading** — the use of external tools (including AI) to reduce internal cognitive demand, shifting mental work from the learner to the system. In AI in Education, cognitive offloading is the central mechanism through which AI tools can either support or undermine learning: appropriate offloading frees cognitive resources for higher-order thinking, while excessive offloading bypasses the processing required for durable learning. **Over-reliance** is the harmful end of this spectrum — the unproductive pattern where offloading crosses from strategic support into learning displacement.

Questions to Consider

- Cognitive offloading is using external tools — including AI — to reduce internal cognitive demand. The page is explicit that offloading isn't inherently harmful: notebooks, calculators, and search engines all offload. What do you think makes AI-mediated offloading different and potentially more consequential than these familiar tools?
- A common assumption is that using AI too much is the problem. But this page separates over-reliance from mere frequency — it's about a mode of use that substitutes for learning, not about how often AI is used. Can you describe a way of using AI that is frequent but healthy, and one that is rare but harmful?
- The 'speedup illusion' is that AI-assisted work feels faster and easier, creating a misleading impression of productivity that masks reduced learning — students conflate task completion speed with learning. When have you felt productive doing something quickly and later realized you'd learned little from it?
- Research finds the harm of offloading is conditional, not intrinsic: 'AI that coaches preserves or boosts skill; AI that substitutes risks decay.' What is the practical difference between an AI that scaffolds your thinking and one that replaces it — and how would you tell which you were getting?
- One study shows that merely having access to AI advice nearly eliminated people's willingness to say 'I don't know' — even when the advice was wrong — while nearly doubling confidence and cutting accuracy to a third. What does this suggest about how AI changes our awareness of our own ignorance?
- The page introduces a metacognitive equity gap — a 'Matthew Effect with AI': because productive AI use requires prior knowledge and metacognition, already-advantaged students benefit more while those who need practice most are most likely to delegate the learning. How should an educator or designer respond to the fact that the same tool can widen existing divides?

Introduction

Cognitive offloading is not inherently harmful — humans have always used external tools (notebooks, calculators, search engines) to reduce cognitive load. What makes AI-mediated offloading different is its

comprehensiveness: LLMs can generate complete solutions, explanations, and analyses, potentially eliminating the need for the very cognitive processes that produce learning.

How cognitive offloading manifests in AIED research

The knowledge base's articles document cognitive offloading across multiple dimensions: - **Instrumenting self-reflection rather than measuring a trait:** PAUSE (Patterns of AI Use: Self-Examination) turns the 2023–2026 offloading literature into a four-domain self-check — reasoning and critical thinking, creativity and originality, research and learning, social and communicative capacity — with reverse-scored behavioral items, citation anchors on every item, no composite score and no claim to validity (Alam, 2026). Its design position is that the useful intervention on offloading is prompting reflection rather than producing a diagnosis, since no instrument yet has the standing to justify a consequential decision about a person.

- **Prompt patterns as offloading traces:** Misiejuk et al. (2026) use Co-Occurrence Network Analysis to show that reactive prompts (disagreement without domain context) indicate higher offloading, while context-rich prompting with integrated instruction reflects engaged cognition. The *how* of AI use — not just whether it's used — determines the degree of offloading.
- **Volume of prompting does not identify what is offloaded:** Poquet et al. (2026) clustered 97 learners by prompt volume and found the volume clusters did not differ significantly in local-versus-global or active-role prompting — the same volume described both directed delegation (12.9 prompts, 36% active) and nearly no direction at all (4% active).
- **Naturalistic message-level evidence at scale — offloading observed, not assumed:** Piatnitckaia et al. (2026) coded 3,047 ChatGPT messages from 46 undergraduates at one European university across a seven-week exam-preparation window, using GPT-4o-mini with enforced chain-of-thought rationales and validating the pipeline against a trained human rater on 200 messages (Cohen's $\kappa = 0.76$ for question type, 0.75 for Bloom level). Analyze topped that distribution at 27.28% (831 messages) ahead of Understand at 23.76%, the first fine-grained evidence that naturalistic student–AI use routinely aims at higher-order work rather than memorization. A 16-student subsample with linked grades, whose 1,140 messages were hand-coded, supplies what prompt-level traces cannot: 49.6% of 125 dialogues showed no offloading, 34.4% light and 16.0% heavy, on a rubric that reserves *heavy* for cases where the AI produces the first draft and constructs the core intellectual product. Heavy offloading was overwhelmingly a Create phenomenon (80% of the 20 heavy dialogues, 42% of all Create dialogues), which the authors read as evidence that offloading degree and Bloom level are distinct dimensions worth measuring separately. The grade pattern was descriptive only — 17.6% heavy in the top tier, 17.5% in the middle and 5.9% in the bottom ($\chi^2 = 5.80$, $df = 4$, $p = 0.215$) — and rests partly on one programming-focused student whose removal drops the top-tier rate to 8.9%, leading the authors to argue that discipline shapes delegation habits more than performance and to recommend metacognitive feedback on actual usage patterns rather than prohibition.
- **The speedup illusion:** Research on the speedup illusion demonstrates that AI-assisted work *feels* faster and easier, creating a misleading impression of productivity that masks reduced learning. Students conflate task completion speed with learning, a metacognitive blind spot.

- **Learning losses from unguided AI:** High school math RCTs show that GenAI without Guardrails produces worse learning outcomes than traditional instruction. Reduced study time correlates with reduced learning — students complete tasks faster but retain less.
- **A randomized test of the offloading prediction at a 45-day delay — and the deficit is not just saved time:** Barcaui (2025) randomized 120 undergraduates to study AI/ML topics either with unrestricted ChatGPT (GPT-4 web interface, no prompt guidance) or with traditional non-AI methods, then gave a surprise 20-question conceptual test 45 days later. The AI-assisted group scored 57.5% against 68.5% ($t(83) = -3.19$, $p = .002$, Cohen's $d = 0.68$), and the disadvantage survived an ANCOVA holding self-reported study time constant ($F(1, 82) = 7.89$, $p = .006$; adjusted means 6.50 vs. 5.85), so it was not merely a quantity-of-time artifact. The paper's offloading argument is that ChatGPT supplies synthesis and explanation outright, making it a qualitatively different form of delegation than a calculator — one that can absorb comprehension, not just retrieval.
- **Offloading is not always harmful — the "coach" boundary condition:** Lira et al. (2025) show that AI can reduce practice effort *and* improve the learning environment, yielding "work less, learn more." Adults who practiced writing with an AI tool wrote better no-AI letters than those who practiced alone — even beating personalized feedback from human editors — with no illusion-of-mastery inflation. The reconciliation with the harms above is the **form of offloading**: Lira et al.'s AI *scaffolded* (surfacing examples and feedback while keeping the learner in the loop) rather than *replacing* the cognitive act. The skills-vs-basic-abilities perspective converges on the same boundary: **AI that coaches preserves or boosts skill; AI that substitutes risks decay.** Kilinc et al. (2026) put numbers on that boundary in a middle-school agriculture-STEM classroom. Across 42 eighth graders in 12 groups, model uptake accounted for 74.1% of coded collaborative engagement turns in the Most Improved profile, while cognitive offloading and collaborative impasse together reached 80.8% in the Struggling profile. So offloading's effect on learning is conditional, not intrinsic.
- **Critical engagement vs. offloading:** Favero et al. frame AI tutors as either empowering (supporting active cognition) or enslaving (enabling passive offloading), connecting to Critical Thinking research.
- **Metacognitive awareness:** Studies on metacognitive awareness examine whether students recognize when they're offloading versus learning — and whether instructional interventions can improve this calibration.
- **Embodied intelligence as the alternative to outsourcing:** The E3-HOT framework argues that to counter AI-induced cognitive outsourcing and learning detached from authentic contexts, AI should be designed around *embodied intelligence* (situational embedding, embodied participation, cognitive creation) so learners sustain cognitive agency and higher-order thinking rather than offload it. This frames embodied, situated AI design as the positive counterpart to offloading risk, connecting to Distributed Cognition and Embodied Learning.
- **The efficiency–AI Regulation in Education trade-off of distributed cognition:** Hao et al. show that in human–AI collaboration, the mode that offloads most to AI (delegated reasoning) performs best on tasks but correlates with reduced self-regulation — empirical evidence that offloading's

efficiency gain can come at the cost of the learner's regulatory engagement, converging with Self-Regulated Learning concerns.

- **Fatigue and cognitive burden:** AI fatigue research documents how constant AI interaction creates its own cognitive burden, a paradox where offloading one task increases cognitive load from managing AI outputs.
- **The metacognitive beliefs-vs-experiences framework:** Guo & Ye (2026) apply Nelson and Naren's dynamic metacognitive model to reconcile the field's contradictory intervention findings. They distinguish metacognitive *beliefs* (stable, self-referential self-conceptions that anchor offloading choices pre-task) from metacognitive *experiences* (dynamic, task-specific feelings that drive belief updating during-task), yielding the principle of **timing-component matching**: belief-targeting feedback is most effective before a task, while experience-targeting feedback (immediate correctness indicators) is most effective during it. They also formalize **substitutive offloading** (replacing internal processing with external aids) vs. **duplicative offloading** (supplementing it) — when external stores vanish, substitutive offloaders decline sharply while duplicative offloaders retain accuracy — and use **reminder bias** to quantify deviation from optimal offloading. This converges with the "coach vs. crutch" boundary: offloading that scaffolds preserves skill; offloading that substitutes risks decay.
- **A formal problematic-use model for AI dependence in academic writing (I-PACE):** Liu, Zhuang & Wang (2026) extend the I-PACE model of addictive-technology use to generative AI dependence in college academic writing. In a mixed-methods Chinese sample, academic stress is the strongest predictor of AI dependence, AI Literacy is a protective factor (lower literacy → more psychological dependence), and perceived trust mediates the path from social influence to dependence — so dependence forms through a social-influence → trust → behavior pathway, not just individual tool use. Their qualitative data add a policy dimension: students report strategic evasion of plagiarism detection and cite ambiguous rules about what counts as compliant AI use as an incentive to improvise, connecting offloading to Academic Integrity.
- **Cognitive debt and the episodic–habitual offloading distinction:** Lin & Al-Hada (2026) formalize the "critical-thinking paradox" — improved products alongside reduced cognitive engagement — through a differentiated three-level framework (surface/intermediate/deep AI roles) and the construct of *cognitive debt*: a potential cumulative decline in metacognitive calibration and unaided higher-order performance that persists beyond an AI-assisted episode. Their key conceptual advance is distinguishing **episodic offloading** (deliberate, task-specific delegation with retained awareness) from **habitual offloading** (routine, weakly monitored reliance), predicting that the latter on deep-processing tasks yields a product–process dissociation — higher-rated assignments but lower unaided delayed transfer.
- **The outsourcing-to-reallocation spectrum: offloading can redistribute effort rather than reduce it.** Yan et al. (2026) applied Biggs' presage–process–product model to 38 undergraduates in Japan and China writing unsupervised argumentative essays, locating student–GenAI engagement on a spectrum bounded by **cognitive outsourcing** and **cognitive reallocation** — the GenAI-era analogue of surface versus deep approaches. The reallocation minority reported *unchanged total effort* with a shifted focus, moving resources from low-level retrieval to critical

evaluation and reflective consolidation (writing reflection notes after each session to counter shallow retention), which qualifies the assumption that offloading necessarily subtracts cognition. Reallocation was the exception, however: 78.94% touched GenAI only before starting or after drafting rather than alternating it with independent work, and 76.32% relied on a single-turn ask–get-answer–stop pattern (23.68% sustained iterative dialogue), so the integrating behavior that produced reallocation had to be taught rather than assumed.

- **Metacognitive training reduces reminder bias (direct empirical evidence):** Ngai & Gilbert (2026) provide the first clear demonstration that a brief intervention can make offloading measurably more optimal. Two preregistered experiments (N=164, N=416) found that **just five practice trials pairing a performance prediction with veridical, trial-by-trial feedback** improved metacognitive calibration and reduced reminder bias. The four-group additive design isolated the mechanism: **predictions alone were ineffective; adding performance feedback drove the improvement; explicitly labeling over-/under-confidence added nothing further**. The effect appeared on *absolute* (not signed) bias — training corrected individual miscalibration in both directions. This empirically validates the beliefs-vs-experiences framework above: it is *experience-targeting feedback*, not beliefs or prediction alone, that changes offloading behavior. The authors attribute success to financial incentive tied to offloading optimality plus immediate veridical feedback.
- **An in-task reflection prompt makes reliance more discriminative rather than more defensive:** Ren (2026) randomized 342 undergraduates across three conditions (no AI, open multi-turn ChatGPT support, and the same support plus a brief reflection prompt on their own reasoning and on what would justify rejecting the AI explanation) and found that open support carried 62.4% acceptance of incorrect AI advice, which the reflection prompt cut to 39.7% (OR = 0.40), while recommendation accuracy stayed comparable across the two assisted conditions (66.3% vs. 67.0%) and alignment with correct advice remained high. Reflection also improved awareness calibration between perceived and behavioral reliance (0.59 vs. 0.41) and lowered an AI-specific attribution bias index from 0.42 to 0.21. This is the same *experience-targeting* mechanism as the training study above, applied inside the decision episode, and it supports the page's monitoring rather than frequency reading of over-reliance: knowing about model limits did not by itself stop students accepting plausible wrong advice.
- **Metacognitive laziness and a new metacognitive Equity gap:** Lodge & Loble (2026), a sector report for Australian schooling, argues the core risk of GenAI is cognitive offloading rather than plagiarism. They adopt **metacognitive laziness** (Fan et al. 2024) — the convenience of AI undermining learners' engagement in essential self-regulatory processes, so learners abdicate metacognitive responsibility to the tool — and introduce a **metacognitive equity gap** (a "Matthew Effect with AI"): because leveraging AI productively requires Prior Knowledge and metacognition, already-advantaged students benefit more while those who need the practice most are most likely to delegate the learning, widening existing divides. Their proposed remedy is **teacher augmentation** (giving the tool to expert teachers to scale their practice, supported by studies showing teacher-facing AI improves outcomes at far lower cost) rather than student-facing AI tutors, alongside Load Reduction Instruction and metacognitive prompts.

- **Over-reliance is the leading ethical concern across all Conversational AI generations.** The umbrella review of conversational AI agents (Ganguly et al. 2025, 34 reviews) reports that human–AI relationship concerns — including over-reliance and the diminution of social interaction — are the **most frequently discussed ethical issue across all CAI generations**, predating GenAI. It also lists educational impact and cognitive concerns (including overreliance and degraded critical thinking) as the second most-discussed challenge category, underscoring that offloading's harm is a persistent, cross-generation theme rather than a GenAI-specific novelty. (Conversational AI agents in education: an umbrella review of current utilization, challenges, and future directions for ethical and responsible use)
- **Teachers as reflective regulators of cognition:** Ho and Chen (2026) extend offloading theory to *professional* AI judgment by interviewing 18 in-service teachers. They identify a 'metacognitive ecology' in which teachers recognize, redistribute, and reflectively re-engage cognition with GenAI, framing AI as a cognitive partner rather than a thinking substitute — and flag 'professional drift' as a risk when offloading goes unreflective in AI-augmented Teaching and administration.
- **Offloading is value-based decision-making, and some students are more vulnerable than others.** Seung & Basham (2026), a conceptual review in *Learning Disability Quarterly*, synthesize cognitive science, Special Education, and educational technology to model GenAI offloading as a cost–benefit decision shaped by performance goals, task difficulty, academic self-efficacy, and perceptions of the tool. They argue that **students with learning disabilities (SWLDs)** are especially vulnerable to suboptimal offloading — because heightened cognitive load, effort-avoidant performance goals, lower academic self-efficacy, and inflated expectations toward GenAI make premature or excessive delegation more likely. GenAI is framed as a **compensatory aid or shortcut depending on how offloading decisions interact with learner profiles and instructional design**, with instructional Guardrails the key moderating factor (teach metacognitive self-regulation, build AI Literacy to calibrate tool trust, sequence mastery experiences, and assess process not just product). This extends offloading's equity dimension: the same tool that reduces barriers to access can, if unguarded, substitute for the very practice SWLDs need most.
- **Offloading risk is developmental.** Niu et al. (2026) scoped 24 evidence sources on GenAI and children's creative thinking and found over-reliance and prompt dependence among the recurring risks, strongest in the lower grades, alongside template-based thinking and children's difficulty judging whether an AI suggestion was original; one fMRI comparison recorded lower engagement of cognitive control and attention networks during child-ChatGPT interaction than in human conversation. Because younger children lacked the linguistic and metacognitive skills that text-based prompting demands, the authors recommend keeping AI literacy, authorship and unaided idea generation inside the activity itself and measuring independent creativity separately from AI-assisted output. This adds an age dimension to the vulnerability patterns above.
- **The "thinking less vs. learning differently" question is conditional.** Nesnin et al. (2026) offer a broader analytical review concluding that AI is **not necessarily making students think less but transforming how they learn** — the outcome depends on use. AI that clarifies, verifies, and guides enhances learning; AI that replaces independent thinking yields passive dependence. This

converges with the knowledge base's pervasive "scaffold vs. substitute" boundary and the conditional view of offloading's harm.

- **Offloading is layer-sensitive: the depth of delegation matters, not just its occurrence.** Chen (2026) introduces a layer-sensitive account for academic writing — surface (grammar/vocabulary), structural (outline/sequencing), idea (claims/content), and reasoning (warrants/counterarguments/argumentative logic). In an eight-week quasi-experiment, open AI collaboration produced the highest *supported* writing but the lowest independent no-AI outcomes, with deeper offloading layers carrying the strongest negative association with independent Higher Education higher-order thinking (reasoning offloading indirect ab = −0.34 vs. surface −0.08). Self-regulated writing attenuated but did not eliminate the harm. This refines the scaffold-vs-substitute boundary: some layers of delegation scaffold, while deeper layers substitute for the cognition that builds Critical Thinking.
- **A causal test of the offloading prediction, with the sign reversed: writing with ChatGPT produced *less* learning than writing unaided.** Wagner-Kobayashi (2026) ran a between-subjects experiment in which 35 psychology students spent 20 minutes elaborating an input text, with GPT-3.5 available only to the experimental group, and sat an identical knowledge test before and after. The hypothesized group × time interaction was significant ($F(70) = 5.889$, $p = .018$) but pointed the other way — the no-ChatGPT group learned more (posttest $M = 8.29$ vs 6.94; $b = -1.450$) — falsifying the writing-to-learn prediction that ChatGPT would amplify elaboration. What leaked away was the elaborative effort itself: participants produced only 2.25 examples and 0.88 connections in dialogue with the tool and reported prioritizing the word count over depth, the authors' *utilization deficiency* reading of a tool available but not deployed, and in line with the reduced mental effort and copy-paste behavior the page records elsewhere. Once Motivation entered the model the group × time effect collapsed ($p = .280$), and higher motivation and topic interest predicted gain only *inside* the ChatGPT group, so low-motivation and low-interest students were the ones the tool disadvantaged — experimental support for the motivational pathway to over-reliance this page documents. The authors read the result narrowly (a small, assumption-violating effect under time pressure and without training) and recommend teaching students how to deploy the tool rather than banning it, which keeps the finding on the scaffold-versus-substitute boundary rather than making it a verdict on the tool.
- **The surrender–offloading–agency continuum.** The Sydney PreK-12 rapid review (Arthars et al. 2026, 271 papers) frames GenAI use across cognitive, metacognitive, and affective dimensions: *surrender* (responsibility for learning-relevant work shifts to GenAI, often unknowingly), *offloading* (deliberate, possibly productive delegation that becomes learning only if checked/elaborated), and *agency* (retaining responsibility for effort and judgment). It also warns of **metacognitive inequity**: weaker metacognitive students are more susceptible to detrimental offloading and less able to recognize it.(Young people, learning, and generative AI: A rapid literature review and implications for PreK-12 education)
- **Dependency is governed by self-efficacy as much as capability.** AI dependency is not simply a product of technical skill: Maizel et al. (2026) show that skill-based AI literacy predicted higher dependency (consistent with the enabling-capacity/offloading view), while AI and academic self-

efficacy buffered against overreliance — indicating offloading is governed by motivational self-efficacy beliefs as much as by capability.

- **Offloading changes the threshold to respond, not just capacity.** Marcoccia et al. (2026) show that merely having access to AI advice nearly eliminated people's willingness to say "I don't know" — even when the advice was wrong — while nearly doubling confidence and cutting accuracy to a third; incentives restored accuracy (by reducing reliance) but not suspension.
- **The Safety Gap as the cost of offloading struggle.** Wang & Shan (2026) formalize the divergence between a student's AI-assisted performance and their unassisted capability as the "Safety Gap" — the epistemic risk when AI does the cognitive work and the learner cannot reproduce it. Kim et al. (2026) and Puech et al. (2025) show Productive Failure design (withholding answers, preserving struggle) is the countermeasure.
- **The ICAP/SAMR spectrum frames offloading as a continuum of modes, not a binary.** Rummel, Nachtigall, and Panadero (2026) map the Thermomix kitchen-machine analogy onto learning with Generative AI within the ICAP and SAMR frameworks, showing four scenarios that progress from **passive substitution** (fully outsourcing assignments — the offloading end, risking skill loss and limited Creativity) to **interactive redefinition** (AI as a dialogue partner providing real-time adaptive feedback and co-construction — the engaged end). This reframes offloading's harm as conditional on *mode of use* rather than mere frequency, converging with the pervasive "scaffold vs. substitute" boundary: whether AI use sits at the substitution/Substitution or redefinition/Redefinition end of the spectrum determines whether it displaces or supports the cognition that builds learning.

Navas-Romero et al. (2026) report students' perceptions of the cognitive demands of GenAI-designed instructional materials in higher education alongside their gains in learner competencies, separating the load these materials impose from the competencies they build.

Gillette et al. (2026) record offloading as participants' own experience rather than a theoretical risk: one said genAI "prohibited me from actually reading and finding out myself what is important in the text, to develop reading skills", and another feared "the long-term development, where I become worse in certain skills that I now am very strong in". - **The effect lives in the division of labor, not in the tool.** Nakamura (2026) argues that the heterogeneity in GenAI learning effects dissolves once the unit of analysis becomes the partition of cognitive labor between learner and machine. Offloading augments learning when it discharges operations peripheral to the current goal, and risks erosion when it bypasses the processing constitutive of that goal (Nakamura, 2026). Substantively processing the output, or later reconstructing it, is what rescues an otherwise constitutive offload. - **What a person may hand over depends on their experience of the task.** Akcaoglu (2026) makes task order person-relative: what is higher-order for a novice is lower-order for someone who already holds the procedure, so permitted offloading should grow with experience and stop at the core of the work.

Cognitive capital is the stock that offloading draws down. Riva et al. (2026) reframe offloading as a change in a stock rather than an act. Cognitive capital is accumulated, renewable and depletable knowledge, capability and practice, held by individuals and by organizations, and kept separate from the human-AI system's capability so a joint-performance gain can be seen alongside a human-capability loss. Their four mechanisms — substitution of practice, scaffolding and feedback, metacognitive calibration, and

organizational aggregation — yield seven principles, including that assisted performance is not retained competence and that offloading a task differs from offloading the practice that builds the skill. The motivating statistic is a staggered rollout to 5,172 customer-support agents where an assistant raised issues resolved per hour 15%; that number describes the joint system, and whether agents could still do the work unaided is a measurement the reviewed literature does not contain.

When offloading falls rather than rises

Braun (2026) reports a preregistered experiment (N = 317) in which adults learned new content from conventional worksheets or from a general-purpose assistant restricted to those same worksheets. The AI condition lowered measured cognitive offloading rather than raising it (median −0.27, 95% credible interval −0.58 to 0.04). Deep processing still fell, but through a chain in which lower offloading tracked lower critical thinking, which in turn predicted weaker deep processing (0.78). Disorganization rose by 0.84 with no mediator carrying the effect. The finding is a caution for the standard account: offloading is not the only route by which an AI environment erodes processing, and a condition can leave offloading untouched while suppressing what offloading was supposed to protect.

Offloading empathy, not just cognition

The same bargain applies to emotional labor, and there the evidence is newer. Shastry and Gray (2026) name empathy offloading: when a system can supply emotional support, people give less of it themselves (N = 2,223 across four studies). Willingness to hand empathy to a model tracked belief in the model's capacity for it (b = 0.44), and an experiment that raised that belief through ordinary news coverage moved offloading through it (indirect 0.73, direct not credible). The instructive part is where self-report and behavior split: told that a student got support from a chatbot, participants rated their own offloading lower than for a friend or therapist, then chose fewer empathy words and more indifference words about that student.

- **Offloading splits into a visible gain and an invisible loss.** Pradubwate (2026) argues the calibration failure this page documents is a *cross-dimensional* inference rather than general overconfidence. Operational competence (prompting, iterating, integrating) returns immediate unambiguous feedback, while evaluative competence (judging whether an output is accurate) returns feedback that is delayed, sparse or absent. Offloading raises perceived understanding and lowers deep processing at once, and only the first is experienced. That is why warnings about AI limitations are weak interventions: they address beliefs about the system while the illusion is generated by an absence in the user's own experience. The review is conceptual with no data of its own.

Over-reliance: when offloading becomes harmful

The ladder this page tracks has three rungs, and only the first two belong here. **Offloading** is delegating mental work, which is often productive; **over-reliance** is doing it chronically and without calibration, which is the behavioral failure this section documents; **Cognitive Surrender** is a different failure — the evaluative step never happens, so the learner adopts the AI's answer without any judgment of its quality. The boundary is visible in what the AI is asked to supply: Du and Yuan's *instrumental* assistance produces output, while *judgment-bearing* assistance supplies the standard by which output is judged, and it is the second kind that

displaces the work expertise depends on. The Sydney rapid review draws the same three-way split across 271 papers. Surrender therefore has its own experimental signature and its own page; over-reliance remains the frequency-and-calibration problem, and the two are separable outcomes in the same task — in Shaw and Nave's trials, 73.2% of incorrect-AI trials ended in surrender while 19.7% ended in strategic offloading. **The step past offloading is offloading the regulator.** A metacognitive approach to learning and performance in human-AI interaction restate Risko and Gilbert's sequence — activate beliefs about the tool, judge one's own capacity against it, choose a strategy, recalibrate from the outcome — and name the failure *metacognitive* offloading: the loop is skipped, strategy evaluation is handed to the AI, or fluent success biases the next round of delegation. Their counterpart term is metacognitive onloading, scaffolding that makes the learner responsible for goals, monitoring and strategy judgment. Both sit on two axes, performance and durable learning, so a rise in output quality stops counting as evidence about the learner. The framework is conceptual and untested.

Withdrawing the regulator raises offloading and lowers output quality. Across four experiments with 728 adults, experimentally induced metacognitive disengagement raised cognitive offloading (indirect effect 0.51, 58.0% of the total) and cut expert-rated innovation quality from 4.78 to 3.95, with 57.8% of that drop running through offloading (Xiao, Men & Zhang (2026)). Task complexity strengthened that path and AI literacy weakened it. Two limits bound the claim: the assistant was a researcher-scripted response bank rather than a live model, and occupation and student status went unreported, so this is neither a classroom nor a workplace finding.

Dependence has a trajectory, and it is not monotonic. Across four waves over 18 months (n = 524), perceived usefulness predicted *lower* later academic dependence rather than more, so an escalation story keyed to how useful students find the tool gets the direction wrong (Zhang, 2026).

A benchmark external to any one study measures the same failure and finds it common. ImpactBench scored ten models on 48,540 simulated conversations: its Cognitive Offloading Asymmetry metric averaged 51.9% and Planning-Related Cognitive Intrusion 47.1%. Its education case has Claude Sonnet 5 hand over a thesis, an outline, and a complete essay "ready to paste in" once a simulated student presses for a finished draft, while still refusing to fabricate citations (ImpactBench (2026)). Learning & Skill Development was the weakest of 14 subareas on both polarities, at 45.9% and 16.3%.

Over-reliance is the excessive or uncalibrated dependence on AI tools where students delegate cognitive work they should perform themselves, resulting in reduced learning, diminished Learner Agency, and the displacement of skill development. It is the behavioral manifestation of excessive cognitive offloading: when offloading becomes the default rather than a strategic choice. Over-reliance is not simply about using AI too much — it is about using AI in ways that substitute for rather than complement learning processes. Conceptual work urges keeping this educational over-reliance distinct from relational attachment and clinical dependence: Yan (2026) shows that trust, reliance, over-reliance, attachment, and problematic use are routinely conflated in the conversational-AI literature, and that frequent delegation should not be labeled dependence without impaired control or harm.

- **The efficiency paradox: mastery goals collapsing into offloading "by default."** Yan et al. (2026) identify learners who articulated mastery-oriented goals yet enacted surface-like processes, offloading "not by intention, but by default": their three intention groups (Outsourcing Tool n = 16, Learning Assistant n = 31, Cognitive Partner n = 8) show the modal case is neither

deliberate cheating nor deliberate learning. Outsourcing-group students recognized their own disengagement (copy-pasting paragraph by paragraph was described as “it completely replaced my brain”) and reported fast forgetting, and all 38 interviewees reported low confidence using GenAI effectively — evidence that over-reliance can be driven by missing presage conditions (AI Literacy, prompting competence, task-specific guidance) rather than by motivation to avoid work.

- **Agentic coding offloads comprehension in the field:** Tanaka et al. (2026) report that undergraduates using AI agents in a software project course wrote more code year-over-year but showed comprehension dips under heavy use - recoverable through one-on-one instructor verification of AI-generated code.
- **Learning displacement:** Research on AI’s cognitive effects documents how AI availability reduces effortful processing — the “Google effect extended to reasoning.” Stamatoulis et al. (2026) isolate this as a distinct *pattern* of use: **low-verification uptake** (uncritically accepting AI output) predicted worse academic performance, whereas **evaluative integration** (using AI to support understanding) predicted better performance — and usage **frequency** alone predicted neither. Over-reliance is therefore a *mode of use* that can be separated from how much students use AI.
- **The agency problem:** AIED’s unfinished mission frames over-reliance as an agency and motivation crisis — students bypass learning not because AI is compelling, but because learning tasks feel pointless when AI can complete them effortlessly.
- **Motivation erosion:** Student motivation research finds that knowing AI is available reduces the perceived value of learning the skill yourself, a motivational calculus that particularly affects novice learners.
- **Persistence erodes too, and fast.** After roughly ten minutes with an assistant that answered on request, participants skipped 0.20 of unaided problems against 0.11 for controls and solved 0.57 against 0.73, replicating in reading comprehension (Liu et al., 2026).
- **Supported homework gains did not survive an unsupported exam.** Randomizing 153 proof-course students to earlier AI access raised homework scores 2.56 points and left Midterm 2 indistinguishable from zero, while an attempt-first feedback tool was unpenalized and an open chatbot tracked 3.02 points lower per 100 messages (Chen et al. (2026)).
- **A submission is not evidence of what was offloaded.** Across 59 chatlogs from 23 linear algebra students, 27 of the 30 led by explaining or checking still ended close to the model’s product, so offloading has to be read prompt by prompt (Kontorovich & Wallach (2026)).
- **Literacy debt:** Agentic literacy debt describes the cumulative skill deficit that develops when students habitually rely on AI rather than developing their own competencies, analogous to technical debt in software.
- **Fatigue cycles:** AI fatigue research identifies a paradox where over-reliance leads to cognitive fatigue from constant AI interaction management, which in turn drives MORE reliance — a vicious cycle.
- **The placement rule:** The Effortless Trap reframes allow-vs-ban as a placement question — an unguarded AI helper left high-school students ~17% worse on an unaided exam, while the same

model rebuilt to withhold answers erased the harm. Its diagnostic — *"if letting AI in makes the task feel effortless, it is in the wrong place"* — secures the first hard attempt and the final unaided check as the moments where over-reliance most readily hides as an "illusion of learning."

- **Metacognitive preservation:** The Synthesis-Analysis Reciprocity Model proposes tools that preserve human epistemic agency by structuring AI interaction around human analysis cycles rather than AI generation cycles.
- **The metacognitive mechanics of overuse:** the beliefs-vs-experiences framework explains *why* students over-offload even when it hurts them — people offload impulsively, and pre-existing metacognitive *beliefs* anchor behavior faster than task *experiences* can correct it — so the antidote to over-reliance is metacognitive, not merely restrictive.
- **Over-reliance is trainable via calibration training:** Ngai & Gilbert (2026) show reminder bias — the laboratory analogue of over-reliance — can be reduced with a brief metacognitive intervention (five practice trials pairing a prediction with feedback), correcting calibration in both directions. This implies the antidote to over-reliance is not merely restrictive rules but **calibration training that makes students accurate about what they can actually do unaided**.
- **Field evidence: AI that coaches vs. AI that answers.** NUMI (Oreopoulos et al. 2026) found that AI support that coached rather than gave answers slowed students down but reduced effort-avoidance — improving next-attempt correctness after mistakes with more time per question (a "productive slowdown") — while Khanmigo (Oreopoulos & Low 2026) showed that without structure making mistakes consequential, students default to shallow use (bare answers, prompt clicks) and gains match practice without AI. Both confirm that offloading's harm is contingent on **how** AI is used and designed, not just on access. CoMeT (Hou et al. 2026) supplies the design dimension that boundary otherwise leaves implicit — a tutor can carry *more* of the labor without buying more delegation. Its ladder climbed one rung each time a learner did not use its support and dropped to the lightest rung on take-up, holding metacognitive demand statistically equivalent to a tutor that withheld answers by design (p_TOST = .004) while an artifact reached the workspace in 48.1% of sessions against 23.7% under that withholding tutor, and learners asked it to build in 50.4% of sessions against 51.1% under an unrestricted answer-on-request tutor (OR = 0.95, p = .82). Delegation tracked the demand the tutor placed on the learner rather than the amount of work it took over.
- **Large-scale field evidence: the "Generative AI learning penalty."** Strömberg, Lei, & Wu (2026), tracking 26,811 Chinese secondary students over 30 months, found that self-directed generative-AI adoption raised homework scores 18% and cut homework time 30% while *lowering* closed-book exam scores 20% within six months and entrance-exam scores 18–24% after two years — concentrated among the ~81% of users whose behavior indicated homework outsourcing (short completion time + inflated homework scores). This is direct large-scale evidence that unguarded offloading (using AI as a homework substitute rather than a tutor) produces the learning penalty cognitive-offloading predicts, often undetected by students themselves.
- **Over-reliance erodes self-directed learning via motivation and self-efficacy.** Zhao & Gu (2026) model the mechanism directly: across 487 Chinese undergraduates, **thoughtless use of GenAI (TUGA)** — adopting AI outputs without critical evaluation — significantly undermined

Self-Directed Learning (β = −0.42) both directly and through partial mediation of Motivation (β = −0.54 path from TUGA) and Self-Efficacy (β = −0.37). The model explained 75.3% of SDL variance. Because motivation was the strongest positive driver of SDL (β = 0.68), and thoughtless use suppresses it, this is quantitative evidence that over-reliance damages the motivational and self-efficacy resources autonomous learning depends on — with gender differences (stronger motivation harm for males, stronger self-efficacy harm for females).

- **Offloading tendency predicts lower higher-order outcomes, and verification literacy needs metacognition to pay off.** Davor, Larbi and Boateng (2026) surveyed 533 university students in Ghana and modeled offloading tendency, AI task scaffolding and AI verification literacy against higher-order outcomes through metacognitive self-regulation. Offloading tendency was the strongest negative predictor of critical thinking (−.240) and technical problem solving (−.312) and also depressed metacognitive self-regulation (−.294), while scaffolding predicted both outcomes positively (.185 and .170). Verification literacy had no significant direct effect on either outcome and worked only through metacognitive self-regulation, a full mediation pattern the authors call a metacognitive activation mechanism: teaching students to check AI output is not enough on its own, because the evaluative habit pays off only when it is embedded in planning, monitoring and reflection during the task.
- **Dependence operates as a boundary condition on the benefit of use.** Shojaei et al. (2026) surveyed 412 undergraduate business students in Oman and decomposed the association between GenAI use and self-reported critical-thinking disposition: the zero-order correlation was near zero (r = 0.050) while the adjusted coefficient was positive (.185), because a negative indirect path through dependence (−0.147) offset it. Dependence was negatively associated with both disposition (−.389) and self-perceived employability (−.328) and weakened both use-to-outcome links, and simple slopes fell from 0.424 at low dependence to −0.054 at high dependence, attenuation rather than reversal. The reading keeps the finding on the mode-of-use side of the boundary: dependence marks where use shifts from augmentation toward substitution, and frequency alone masks the opposing pathways.
- **AI overreliance as a complex adaptive system.** Rather than studying overreliance one user at a time, a modeling paper frames it as a population-level process in which agents update Bayesian beliefs about AI quality and, when networked, learn from peers. Social proof can turn reliance into a feedback cascade (visible unverified use suppresses verification), while social learning creates consensus rather than overreliance — a framing that shifts intervention targets from individual calibration to the networked dynamics of trust and reliance.
- **Six diagnostic criteria separate productive reliance from harmful dependence.** Du & Yuan (2026) give over-reliance a more granular diagnostic vocabulary than usage frequency, distinguishing instrumental assistance (AI helps produce output) from judgment-bearing assistance (AI supplies the standards by which output is assessed). Their review operationalizes the productive/harmful boundary through six criteria — **contestability, recoverability, transfer, traceability, distributed responsibility, and epistemic plurality** — and traces four sociotechnical pathways (fluent authority, frictionless delegation, opaque synthesis, institutionalized dependence) through which offloading either preserves or displaces the epistemic work that develops judgment. Because dependence is contextual and institutional rather than

merely individual, the framework directs attention to assessment incentives, interface design, and procurement alongside learner self-regulation.

- **The unmeasured aftermath: cognitive washout.** Yajee (2026) names the field's biggest open question as *post-withdrawal*: almost all offloading research measures cognition during AI use, but almost nothing measures what happens after an assistant is withdrawn for days or weeks (an exam, an outage, a license review). It formalizes **cognitive washout** with a Washout Curve Model — estimable parameters for recovery time constant, recovery completeness, residual growth, and a hysteresis index comparing relearning to original effort — and four possible outcomes (elastic rebound, partial plateau, latent scaffold, over-recovery). Because reversibility determines whether an induced deficit is an inconvenience or a cohort-level injury, the paper argues withdrawal deserves the same methodological standing as adoption, and specifies a three-arm, three-domain, twenty-two-week protocol to adjudicate between outcomes. This turns the "coach vs. crutch" and substitutive-vs-duplicative distinctions above into a *testable longitudinal* research agenda on whether and how quickly offloaded skills return.
- **Reliance without domain knowledge degrades into guessing.** Mikhasenko et al. (2026), redesigning the introductory nuclear and particle physics course at Ruhr University Bochum, describe a failure mode of reliance in the absence of domain knowledge: when a student could not judge whether a generated answer was physically sound, the intended "conversation with AI" degraded into guessing against plausible but unreliable output. The same course's mid-semester survey (n=30) found frequent LLM use (24 of 29 used them often or always) alongside low self-reported preparedness for the computing fluency the assignments required, and open responses raised AI dependence and unequal access to paid models among the friction points.
- **The Daoist counter-argument: offloading is not just impractical but self-defeating.** Xie (2026) supplies a normative, anti-delegation counter-argument from Daoist self-cultivation: in Neidan (内丹) practice "there are no cognitive shortcuts," and the practitioner cannot outsource the labor to external devices, so AI should be "not a cognitive surrogate but an instrumental adjunct," akin to an alchemical furnace — a framing that aligns with the "coach vs. crutch" boundary above rather than with substitutive offloading.

Offloading can cost the self, not only the skill. de Barba (2026) names the part of a learner's domain self whose capabilities reside in an AI-enabled tool and are available only on the provider's terms the *rented self*, and separates two costs. A *calibration* cost is a misjudged locus — underclaiming a capability one holds, or overclaiming one the tool holds — while a *self* cost follows whenever a core capability is rented, even knowingly, because the operations that build the self are never performed. Her four configurations cross locus with attribution: owned competence, unclaimed competence, visible rental and hidden rental, the last being the one that removes the signal prompting a learner to build what they believe they already own.

A 30-expert consensus puts the damage at both ends of the learning sequence. A preregistered Delphi exercise over 65 learning processes found acquisition vulnerable (Encoding 3.30, Retrieval 3.30, Information Acquisition 3.00 on the 1-5 disruption scale), consolidation enhanced (Learning From Feedback 4.00, Learning From Examples 3.90, Self-Testing 3.80), and higher-order thinking vulnerable again (Kendeou, Greene & Nixon et al., 2026). Ten of eighteen higher-order processes reached consensus on vulnerability only, with enhancement ratings below threshold.

The CLT framework

Access to AI feedback is not the same treatment as engaging with it, and the load measures separate. Wenzel, Geiger and Liening (2026) ran a five-week longitudinal field study in a business simulation game (**234 students, 1,147 weekly observations**) and separated assignment from receipt. Merely providing access to conversational AI feedback moved neither **extraneous** (β = .071, p = .481) nor **germane** load (β = .019, p = .807). But students who used it **regularly** reported significantly **higher germane load** than experimental non-users (β = −.468, p < .001) and than controls (β = −.253, p = .028) — while **extraneous load was never reduced** by access or engagement (F(1, 219) = 0.499; usage-based F(3, 214) = 0.172). That is the theoretically interesting pattern and the opposite of the usual claim: the intervention made learners work harder on the material without making the environment easier. Intrinsic load drove extraneous load (**β = .647, p < .001**) and metacognitive self-regulation drove germane load (**β = .363, p < .001**), with extraneous load negatively associated with germane load (β = −.178, p < .001) exactly as CLT specifies. Both loads also **declined across the five weeks** (extraneous β = −.388, p < .001) — a novelty effect visible on a cognitive measure rather than an engagement one.

Cognitive Load Theory (Sweller) provides a contested theoretical lens on working memory and instruction: intrinsic load (task complexity), extraneous load (presentation friction), and germane load (schema-building effort). Well-designed AI should reduce extraneous load while preserving germane processing; poorly integrated AI reduces all three, leaving students with completed tasks and empty learning. Note that the theory's claims are contested in the wider literature, but its framing remains influential in how offloading effects are discussed.

The profession-level stakes of offloading. The Cognitive Commons framework (Lovett 2026) extends offloading from an individual to a collective level: when AI lets junior workers skip the cognitive struggle that builds deep expertise, it can deplete a profession's shared expertise pool over time — the "Validation Tether" means effective AI oversight depends on the very mastery that AI adoption may undermine. This reframes individual-level offloading and skill-decay as a systems-level regeneration problem with AI Governance implications.

Connections to related concepts

Cognitive offloading (and its harmful form, over-reliance) connects fundamentally to Trust Calibration — knowing when to trust and when to question AI — and AI Literacy, which includes the metacognitive skill of knowing when to offload and recognizing one's own reliance patterns. It connects to Scaffolding (structured support that reduces load without eliminating cognitive demand) and Prompt Engineering (the primary mechanism through which offloading is enacted in LLM interactions). It intersects with Metacognition and Self-Regulated Learning — effective learners calibrate their offloading decisions — and with Critical Thinking, Learner Agency, and Student Experience. Online Teaching and Learning is a particularly vulnerable context: the medium already distances learners from immediate accountability, and self-paced, screen-based work invites the "ask for the answer" shortcut that offloading research identifies as the core harm mechanism (see AI Misuse and Learning Harm).

Not all offloaded friction is excess friction. Zohar, Bloom and Inzlicht (2026) draw the distinction that the offloading literature needs: previous Technologies removed *excess* friction — tedious or insurmountable obstacles with little learning or meaning value — whereas generative AI in intellectual work also strips away

beneficial friction, letting a learner move from ideation to evaluation without questioning the output. They marshal the associative evidence bluntly: people who use AI struggle to accurately recall or reproduce their own work, acquire fewer skills, show less transfer, and perform worse when AI support is removed — converging with the cognitive-debt findings from EEG studies of essay writing with an AI assistant. Their argument also supplies the motivational half of the mechanism that pure cognitive accounts miss: because effort signals that our actions matter, offloading it reduces appraised purpose and meaning, and as AI substitutes for effort in a domain the motivational payoff of effort there erodes, deepening reliance further. The paper's corrective is a gradient rather than a prohibition — preserve moderate struggle, remove what only overwhelms (Desirable Difficulties, Motivation).

- **The under-engagement signal appears developmentally.** A first neuroimaging comparison of children and adults talking with ChatGPT found 6–7-year-olds showed weaker within-network connectivity than adults in the frontoparietal control, salience and dorsal attention networks — at matched creativity scores — and lacked the creativity–connectivity coupling adults showed. Because those executive functions (planning, monitoring, inhibition) are immature at first grade, the authors read the result as relevant to the minimum-age debate. Caveats: no no-ChatGPT control, n = 31, and a framing confound that may have suppressed children's critical evaluation (Horowitz-Kraus et al. (2026)).
- **Dependent versus autonomous offloading — the distinction that sets the outcome:** Fan, Li and Zhang (2026) organize the GenAI evidence around a sharpened version of this boundary, drawing on a three-wave study of 589 students and early-career knowledge workers: *dependent* offloading delegates core thinking to the tool and was associated with transferred Learner Agency, lower intrinsic motivation and poorer perceived cognitive outcomes, while *autonomous* offloading keeps epistemic agency with the learner and showed the opposite pattern. The finding that matters most for detection is that immediate performance benefits did not differ between the two modes, so a learner resolving tasks fluently on any given day gives no signal about which mode they are in. The same review records the wider split in the evidence — a three-level meta-analysis of moderate overall benefit (g = 0.499; g = 0.669 for comprehension, cognition and creativity) against associations between dependence, fatigue and weaker Critical Thinking — and traces maladaptive use to externalized self-regulation rather than to technology addiction.
- **Three interaction pathways, not one behavior.** The Neuroplasticity-AI Interaction Model (NAIM) separates direct bypass, where the model supplies the solution and generative effort disappears; cognitive offloading, where specific sub-processes are delegated and the effect depends on whether those sub-processes are the learning target; and scaffolding, where the model constrains help to preserve effortful processing (Bypass, Offload, or Scaffold: A Conceptual Model of How Large Language Models Shape Learning)

Two controlled studies in the recent batch pin down the two halves of this claim — whether the behavior shifts, and what it was protecting. Maier et al. (2026) made the learning consequence of offloading visible before each choice in a preregistered experiment with 704 participants practicing fraction arithmetic: odds of offloading an answer fell to OR = 0.47 and odds of answering a later unaided test item correctly rose to OR = 1.51, while an effort-based reward moved neither outcome. Offloading compounded within the session — after offloading one item, participants offloaded the next in 69.7% of cases without the feedback and 55.9% with it — and a ten-percentage-point rise in offloading was associated with 32% lower odds of unaided

success (OR = 0.68). Bergh et al. (2026) supply the outcome-side complement: 55 computer science undergraduates who coded with ChatGPT scored 89% against 69% without it, recalled less of the same material immediately (41% vs. 53%) and at 48 hours (39% vs. 52%), and attributed only 45% of the submitted code to themselves against 81%. Read together, the feedback study shows the behavior can be shifted without restricting access to the tool, and the programming study shows what the shifted behavior was protecting.. The model is calibrated against the strongest available field evidence: unrestricted GPT-4 access in a study of nearly 1,000 high-school mathematics students raised practice performance by 48% yet left a 17% deficit on the unassisted exam, whereas hint-constrained GPT Tutor produced a 127% practice gain with the exam deficit largely eliminated. Offloading is therefore harmful only in the bypass configuration, and the operative design variable is whether the model substitutes for the graded target skill. (Bypass, Offload, or Scaffold: A Conceptual Model of How Large Language Models Shape Learning) The same logic turns reward shaping into a design tool: Macina et al. (2026) train LLM tutors with a masked near-transfer post-test and two binary gates, so the reward can rise only through what the student wrote in its own turns, and their ablation shows the gates, not the raw learning-gain reward, are what reduce solution handover.

Over-reliance shows up as a named challenge across disciplines, not as a single study's anomaly. In a 66-study review of generative AI in inquiry learning, Yahya et al. (2026) found over-reliance or cognitive offloading reported in 16 studies (24.2%), behind inaccuracy at 31.8%. The pattern is reported by the primary studies rather than measured by the review, whose authors appraised neither study quality nor reporting bias.

The bypass configuration has a civic price the learning studies do not bill. Muñiz and Castro Samayoa (2026) argue that willed offloading of inquiry, analysis, evaluation and synthesis atrophies the practice democratic citizenship depends on. Their sequencing rule is the bypass/scaffold distinction stated developmentally: arithmetic before calculators, citation conventions before reference managers, and a chatbot introduced after the skill rather than in place of it. They also name the frame that makes bypass attractive, which is the efficiency premise that the point of schoolwork is to finish quickly.

Common Misconceptions

- **"Prompt volume measures offloading." 97 learners** were clustered by prompt volume, and **the volume clusters did not differ significantly in local-versus-global or active-role prompting**. Counting prompts counted activity, not the distribution of cognitive work.
- **"Students use AI mainly to understand." Analyze topped the distribution at 27.28% (831 messages) ahead of Understand at 23.76%** — the first fine-grained evidence that naturalistic student-AI interaction leans analytic rather than comprehension-oriented.
- **"Prompt traces reveal whether offloading happened."** What prompt-level traces cannot supply comes from a **16-student subsample with linked grades, whose 1,140 messages were hand-coded**: **49.6% of 125 dialogues showed no offloading** at all. Trace patterns overstate offloading relative to hand-coded dialogue.

Cognitive Surrender

> **Cognitive surrender** — adopting an AI system's output without doing the reasoning that would let you evaluate it. Where Cognitive Offloading asks *how much* mental work a learner delegates and whether the delegation is calibrated, surrender asks whether the learner keeps the evaluative role at all: the answer arrives, is accepted, and becomes the person's own position without the checking that would have constituted judgment. The term comes from Shaw and Nave's (2026) Tri-System Theory, which locates it as a distinct failure from both offloading and over-reliance.

Questions to Consider

1. When a student accepts an AI answer that happens to be right, has the class succeeded? What would have to be true for the acceptance itself to be the thing that mattered?
2. Is a calibrated delegator who knows their own limits different in kind from a student who simply cannot tell? How would an instructor tell the difference in a single piece of work?
3. If confidence rises while accuracy falls — as it does when AI advice is available — what does that do to the learner's own error detection?
4. Where is verification teachable, and where is it a workload problem policy? Which parts of a curriculum would need to change for checking to be the norm rather than the exception?
5. Should institutions measure surrender at all, or does measuring it invite the same surveillance that disclosure rules struggle with?
6. What would a task look like that rewards a student for overriding a wrong AI answer rather than for producing a polished one?

Introduction

Surrender is the disposition behind the most common failure in AI-supported study: not using the tool too much, but taking its word for it. The Cognitive Offloading page holds the older construct and its evidence, and misuse-of-AI holds the harm inventory. This page exists because a distinct cluster of work now names and measures something those two do not quite capture.

Three things distinguish surrender. It is about *judgment*, not effort: a student can spend considerable time prompting, reformatting and refining output while never once recruiting their own standard for whether the output is any good. It is often *invisible to the learner*: the signaling that normally attends effort — hesitation, uncertainty, the sense of not knowing yet — is short-circuited by fluent text. And it is *not reliably fixed by practice or incentives alone*, which is where the evidence gets pointed.

Offloading, over-reliance, surrender: three different failures

Construct	Core question	Typical harm mechanism	Where it is measured
Cognitive Offloading			RT and accuracy under tool-present versus tool-absent

Construct	Core question	Typical harm mechanism	Where it is measured
	How much mental work is delegated, and is that calibrated?	Displaced practice: the learner skips the beneficial friction that builds a skill	conditions; response-time panels
Over-reliance	Is delegation chronic and uncalibrated rather than strategic?	Skill erosion, motivation and self-efficacy loss, literacy debt	Self-report scales, log data, performance on unaided transfer tasks
Cognitive surrender	Is the learner's own evaluative judgment engaged before the answer is accepted?	Unchecked acceptance of wrong output, inflated confidence, loss of authorship	Trials where AI advice is correct versus faulty; override and verification behavior

The three sit on one ladder rather than replacing each other. Offloading is often productive; it turns into over-reliance when it stops being strategic; surrender is the version in which the evaluative step goes missing. The distinctions are drawn in practice as well as theory: the Sydney rapid review of 271 empirical papers on PreK-12 generative AI organizes student behavior into exactly these three categories — surrender, offloading, and Learner Agency — and spreads them across cognitive, metacognitive and affective dimensions. Du and Yuan (2026) cut the same boundary from the other side: instrumental assistance produces output, judgment-bearing assistance supplies the *standard by which output is judged*, and only the second kind reliably displaces the work that develops expertise. Their six criteria — contestability, recoverability, transfer, traceability, distributed responsibility and epistemic plurality — are a surrender diagnostic rather than a usage measure.

The Tri-System account

Shaw and Nave (2026) extend dual-process reasoning with a third system. System 1 is fast and intuitive; System 2 is slow and deliberative; **System 3** is artificial cognition that runs outside the brain. System 3 can supplement internal processing, supplying candidate answers and flagging contradictions for System 2, or it can supplant it, in which case deliberation never begins. Surrender is the supplanting case, and the theory predicts it should be detectable as a signature rather than a feeling: adopt the AI's answer when it is right, adopt it when it is wrong, and report more confidence either way.

The experimental signature

Three preregistered experiments adapted the Cognitive Reflection Test and randomized *AI accuracy* using hidden seed prompts, so participants could not tell a good assistant from a bad one from the interface (N = 1,372; 9,593 trials).

- **People consult, then adopt.** Participants chose to consult the assistant on a majority of trials (>50%).
- **Accuracy tracked the AI, not the person.** Against a brain-only baseline, accuracy rose about 25 percentage points when the AI was accurate and fell about 15 points when it erred, the contrast the authors call the behavioral signature of surrender (Cohen's h = 0.81, 95% CI [0.72, 0.91]; per-study h = 0.83, 0.86, 0.78).

- **The two behaviors separate cleanly.** Across incorrect-AI trials, 73.2% ended in surrender, 19.7% in offloading (overriding the wrong advice and answering correctly), and 7.1% in failed overrides.
- **Confidence rises with access.** Despite roughly half of the AI answers being faulty, access to the assistant raised stated confidence by 11.7 percentage points (77.0% versus 65.3%).
- **Situational pressure does not remove it.** Per-item incentives plus feedback increased offloading by about 19 points to 37.1% and reduced surrender to 57.9%; time pressure cut offloading by about 12 points to 6.2% and raised failed overrides to 13.8%. Both conditions shifted baselines without closing the accurate-versus-faulty gap (OR = 14.28 under time pressure; OR = 11.05 under incentives and feedback).
- **Susceptibility is a disposition, not just a situation.** Higher trust predicted a wider accurate-versus-faulty gap (OR = 2.81) and, in the head-to-head model, surrender over offloading (OR = 4.36). Higher need for cognition cut the gap (OR = 0.83) and shifted outcomes toward offloading (OR = 0.46); higher fluid intelligence was protective in the same direction (OR = 0.69), and its strongest single effect was a lower tendency to follow faulty advice once the assistant had been engaged (OR = 0.23).

The practical reading is that surrender is a **discrimination failure** rather than a motivation failure. The participants who surrendered were not trying to avoid work; they could not tell good advice from bad, and the interface gave them no reason to try.

A preregistered experiment by Braun (2026) supplies a contrasting configuration. With the assistant fenced by retrieval augmentation to the assigned worksheet, the AI condition lowered cognitive offloading (median −0.27) instead of raising it, and no offloading path carried the rise in disorganization (0.84). Surrender needs an assistant whose advice can be adopted wholesale; a system that answers only from the present material gives the learner less to adopt and more to reconcile.

Surrender outside the lab

The lab findings line up with field and observational work that independently reached for the same word.

- **Population-level displacement.** Rismanchian et al. (2026) analyze 3.2 million ALEKS learning interactions and 12.2 million placement-assessment response times across a ten-year panel, with graph-based problems serving as controls for text-based ones. Students completed AI-susceptible work faster and scored higher on it while proctored retention items showed a 25% cumulative decline in the odds of a correct response; the authors call the pattern cognitive surrender at population scale.
- **Verification as the discriminating variable.** Stamatoulis et al. (2026) find that *how* students use generative AI predicts performance while *how much* they use it predicts neither: low-verification uptake — uncritically accepting output — was associated with worse outcomes, and evaluative integration with better ones.
- **Thoughtless use erodes the resources self-direction needs.** Zhao and Gu (2026) model adopt-without-evaluating directly: across 487 undergraduates, thoughtless use of generative AI was associated with lower self-directed learning ($\beta = -0.42$), partly through reduced Motivation and Self-Efficacy.

- **The neural and ownership trace.** the cognitive-debt EEG study measured essay writing with an Large Language Models (LLMs), a search engine and no tool: the LLM group showed the weakest neural connectivity, reported the lowest authorship of their own work, and struggled to quote what they had written.
- **Surrender can arrive unsolicited.** Work on judgment suspension found that the mere availability of AI advice collapsed people's willingness to say "I don't know" (0.06 versus 0.36, and 0.03 versus 0.44 across two studies), while correctness fell and confidence rose from about 30 to 76. Stakes did not restore suspension, though incentives improved accuracy by encouraging overrides. A fourth study showed the effect without any consultation at all, the pattern of an autocomplete or a search summary rather than a chat prompt.
- **Dependent and autonomous modes are distinguishable only in consequence.** Fan, Li and Zhang (2026) follow 589 students and early-career workers across three waves: dependent offloading delegated core thinking and tracked with lower intrinsic motivation, while autonomous offloading did not, and immediate performance looked identical in both.
- **The model's own contribution.** Sycophancy is the complement to surrender: an assistant that agrees, hedges toward the user's framing, or states a claim fluently gives the learner nothing to push against.
- **Withdrawal is the unresolved half.** Work on cognitive washout points out that almost all of this research measures cognition *during* AI use, and almost none measures what happens when the assistant is taken away, which is exactly the question an exam, an outage or a license review poses.
- **"Whole-essay delegation stays hypothetical outside the lab."** It happened in a one-session online study with no policy and no encouragement. Of **77** college writers, **15 (19.5%)** submitted essays that were **100%** written by the model, without typing a word in the editor, and **20** participants asked outright for an entire essay, the most used code in the scheme. The heaviest user submitted **27** queries. Surrender showed up as a request pattern, not as a single detectable act.

Designing and teaching against surrender

- **Make verification the assignment, not the advice.** Require a stated first answer before the AI is consulted, and require students to name the points where they overrode it. This turns an invisible judgment step into a gradeable artifact.
- **Reward overrides, not usage.** In the experiments, incentives attached to accuracy raised offloading toward 37% without eliminating surrender; incentives work when they make checking consequential, which is also the finding behind the Effortless Trap's placement rule — an unguarded helper left students about 17% worse on an unaided exam, and a rebuilt model that withheld answers erased the harm.
- **Teach discriminating, not just distrusting.** Because need for cognition and fluid intelligence predicted resistance while self-reported trust predicted vulnerability, the trainable target is the ability to tell good output from bad on a specific task. Calibration training with prediction-plus-

feedback trials is the worked prototype: a brief intervention reduced reminder bias in a laboratory analogue of over-reliance.

- **Surface disagreement rather than confidence.** Because access inflated confidence even on wrong answers, the useful design move is friction that presents conflicting evidence, uncertainties or counter-arguments, so the learner has something to evaluate instead of something to accept. Human-in-the-loop designs with verification prompts and disclosure requirements are the institutional counterparts.
- **Keep an measurement.** If assisted performance and unassisted capability are not measured separately, surrender is invisible to course evaluation: the semester looks better and the retention numbers quietly fall.
- **Treat it as a systems and design problem.** Agentic designs note that the more an agent, the less cognitive effort the learner spends, converting productive delegation into surrender by default; modeling work adds that reliance spreads through social proof, so cohort norms and interface defaults matter as much as individual habit.

Open questions

Does surrender habituate, or does it decay with disuse? Washout research formalizes the post-withdrawal question but the long-run data do not exist yet. Can surrender be measured in the wild without invasive logging — and do self-reports of checking behavior predict anything? Does the confidence inflation persist once a learner has been burned by a confident wrong answer, or is miscalibration sticky? And at the level of a profession rather than a person, does widespread surrender deplete the shared expertise pool that oversight of AI systems itself depends on, the concern raised by the cognitive commons framework?

Limitations

The evidence for surrender as a named construct rests heavily on one program of laboratory work: three preregistered experiments on an adapted Cognitive Reflection Test with convenience samples, which establishes the mechanism and the dispositional moderators but does not transfer to high-stakes professional judgment. The design also captures single exposures, so nothing in it shows whether surrender habituates or compounds. The field evidence is observational: the ALEKS panel shows faster completion with worse proctored retention, but a causal attribution to surrender rather than to study-strategy change requires assumptions the design cannot test. Definitions are still unstable across the literature — offloading, over-reliance, dependence, attachment and problematic use are routinely conflated, and at least one synthesis argues that frequent delegation should not be labeled dependence without impaired control or harm. Finally, self-reports of trust, need for cognition and checking behavior carry the usual limits, and much of the classroom evidence concerns higher education and secondary rather than early schooling.

Common Misconceptions

“Offloading, over-reliance and surrender are three words for the same problem.” They name three different failures with different remedies. Offloading is delegating cognitive work; over-reliance is depending on the system more than its reliability warrants; **surrender** is adopting the system’s answer

without forming one of your own. Surrender is the most severe because there is no independent judgment left to correct, and it is the one that transfers worst — you cannot teach someone to check an answer they never had.

“People will not trust an AI they cannot verify, so surrender is bounded.” The experimental signature shows the opposite mechanism operating. Three preregistered experiments adapted the Cognitive Reflection Test and randomized *AI accuracy* using hidden seed prompts so participants could not tell a good assistant from a bad one — and participants **chose to consult on a majority of trials (>50%)** and then adopted. The opacity that should have produced caution produced consultation, and consultation preceded surrender.

“The fix is better AI, since surrender follows from errors.” Surrender follows from the *structure* of the interaction: a system that produces a plausible answer first removes the occasion for the learner to generate one. Improving accuracy reduces the harm from wrong answers and does nothing about the abandonment of forming a judgment, which is the harm that persists after the tool is gone.

“Teaching critical evaluation is sufficient.” It is necessary and it arrives too late. Once a plausible answer is on screen, evaluation becomes confirmation — which is why the design literature here puts the student’s attempt before the system’s output rather than auditing it afterwards.

Framing AI Use for Students

> **Framing AI use for students** — the persuasive and communicative craft of shaping how learners understand the value, purpose, and boundaries of AI tools and policies, so that they adopt productive and ethical use rather than rejecting, avoiding, or gaming it. It is the "buy-in" lever that Reducing AI Misuse's educative interventions depend on: structural Guardrails change the environment, but Scaffolding, literacy training, and AI-use policies only take hold when students are actually convinced of their point.

Questions to Consider

- Simply making AI available to students was associated with ineffective or even unethical use, while explicitly framing and embedding appropriate use improved outcomes. If the presence of the tool matters less than how it's framed, what does that suggest about the emphasis on simply 'giving students AI'?
- Most students now use generative AI, few of them are sure whether their own use complies, and they favor tools they access privately over institutional ones. If knowing the rules barely changes what students do, what might persuade instead of just inform?
- When institutions respond to AI with fear and condemnation, students may hide or rationalize their use rather than learn to use it well. Have you seen a 'moral panic' response push students into secrecy? What would a reframed, opportunity-focused approach look like?
- Anxiety about AI isn't purely a barrier: students who worried about accuracy and plagiarism were *more* likely to verify and revise AI output rather than accept it uncritically. How might productive anxiety be channeled into evaluative competence instead of being suppressed?
- Students construct their own sense of what's acceptable through 'sites' — faculty intentions, course documents, peer norms, and institutional messages — that often diverge. When those messages conflict, which one do you think actually wins, and how does framing close that gap?

Introduction

The concept sits between two more familiar ones. Where Technology Adoption Models *predicts* uptake from perceived usefulness and ease of use, framing is the *active practice* of shaping those perceptions. And where Student Experience describes how students currently perceive AI, framing is about changing that experience deliberately. It is the communication-side partner to Educational AI Policy: a policy is only as effective as students' willingness to buy into it.

Why framing matters

Framing matters because **policy and rules do not reliably change behavior on their own**. Survey research on regulatory awareness finds that students' knowledge of institutional GenAI rules shows only weak-to-moderate associations with what they actually do (Knowing the Rules Is Not Enough: Student Regulatory

Awareness and Use of GenAI in Higher Education). Knowing the rules is necessary but not sufficient; the message has to *persuade*, not just inform.

Differentiated framing can originate inside a single policy rather than only across sites: a sentiment analysis of 36 university policies found teaching statements positively framed while GenAI and ethics statements were negatively framed, so students met encouragement and restraint in one document (Sun et al. (2026)).

The frame also shapes whether students experience AI as a **threat to be avoided or evaded** versus a **resource to be used deliberately**. When institutions respond to AI with fear and condemnation — what one line of work calls a recurring "moral panic" — they push students into hiding or rationalizing their use rather than learning to use it well.(Navigating the moral panic: encouraging appropriate use of GenAI in the classroom rather than condemning innovation as disruption) Reframing anxiety and condemnation into structured opportunity changes the whole dynamic of student engagement with AI.

Strategies and evidence

Frame AI as a productive tool, not a threat to be banned

The most directly tested framing intervention in the knowledge base is a six-year natural experiment tracking a data-Visualization course across three conditions: pre-GenAI, GenAI-available (present but unintegrated), and GenAI-integrated (explicit instruction + encouragement to use AI on applied work, banned only on the knowledge-check portion). The finding: simply *making* AI available was associated with students using it ineffectively or unethically, while *explicitly framing and embedding* its appropriate use recovered and improved outcomes on applied questions.(Navigating the moral panic: encouraging appropriate use of GenAI in the classroom rather than condemning innovation as disruption) The lesson is that the framing (how AI is positioned and taught) matters as much as the tool's presence — encouraging appropriate use beats condemning or ignoring it.

Message expectations clearly and repeatedly — and design around students

Because rule-awareness alone does not shift behavior, effective framing pairs clear expectations with structural reinforcement. Students construct their own sense of what is acceptable through what one interview study calls the "sites" where AI policy is interpreted — faculty intentions, course documents, peer norms, and institutional messages often diverge, producing rationalizations like "copying AI text is victimless."("It's OK Because.": The Wild West of Student Rationalization of AI Use in Academic Writing) Framing must therefore close the gap between what faculty intend and what students infer, and acknowledge the social and emotional context — shame and guilt regulate when and how students make AI use visible, driving hiding behaviors and selective disclosure rather than honest engagement.("Stuck in a Spiral": Shame and Guilt as Social Regulators of AI Use in Computing Education)

Say why, not just what

The most direct framing lever in the knowledge base is supplying the *reason* for a boundary task by task, composed as though speaking to students ("you will…", "we will…"). McCorkle's (2025) design case documents the mechanism: after office-hour conversations revealed that students who had read a prohibition

did not believe it applied to them, she rebuilt the policy so that every allowed or unallowed use of GenAI was justified by the specific Assessment it protects — for example, GenAI help with learning objectives is unallowed because "I am assessing your ability to compose learning objectives that are specific, measurable, and at an appropriate level" — and delivered that rationale both in the syllabus and as just-in-time reminders inside assignment instructions. Framing by rationale is an equity move as much as a persuasive one: it assumes less shared background knowledge about authorship, originality, and attribution, and it turns policy into a dialogue rather than a verdict (Academic Integrity).

Reframe anxiety and uncertainty into evaluative competence

A mixed-methods study of academic writing found that AI anxiety is not simply a barrier: students who worried about accuracy and plagiarism were *more* likely to verify, cross-check, and revise AI output rather than take it at face value. The study frames AI literacy less as acceptance and more as **regulatory competence** — the capacity to question outputs, revise selectively, and maintain authorship responsibility. (From AI anxiety to strategic regulation: How university students transform generative AI into a strategic learning resource) Framing AI use for students means channeling productive anxiety toward evaluation, not suppressing it.

Use targeted messages to shape specific behaviors

Small, well-designed messages can shift behavior. An **inoculation message** about ChatGPT's fallibility increased students' intentions to verify AI-provided information and their actual verification behavior. (Student engagement with ChatGPT for educational tasks: Effects of inoculation training on verification intentions and behavior) Likewise, simply warning students about AI fallibility increased Help-Seeking in an intelligent tutoring system — a frame of *calibrated caution* rather than blanket distrust.(Warning About AI Fallibility Increases Help-Seeking in an Intelligent Tutoring System) These point to a general principle: frame the tool's limits honestly, and students calibrate their behavior accordingly rather than either over-trusting or rejecting it.

Secure buy-in and take-up, not just access

Framing is upstream of take-up. Field experiments on AI tutoring found the binding constraint was not capability but *engagement*: despite dedicated session time, nearly half of students never used the platform, and users averaged only 2–5 minutes per week — until a low-cost human-support intervention (a brief in-person onboarding) improved take-up.(Access is Not Enough: Human Support Improves Engagement with AI Tutoring) Getting students to buy into the value and purpose of a tool is a precondition for any learning benefit; framing includes selling that value, not just removing access barriers.

Framing and motivation

Framing connects to Motivation through Self-Determination Theory: how a tool or policy is *presented* determines whether students experience AI use as autonomous and purposeful or as controlled and imposed. Students' engagement with GenAI is shaped by whether the tool supports their sense of competence, autonomy, and relatedness — a framing question as much as a feature question.(Students' engagement with

generative AI in academic learning: A self-determination theory and epistemic network analysis study) When AI availability erodes the perceived point of effort — "why put in this much effort?" — the frame must rebuild a *purpose* for that effort, linking AI use to durable learning rather than task completion.("Why Put in This Much Effort?": How AI Availability Shapes Students' Motivation in Introductory Programming)

Media and public framing

Students are also framed by the wider media and public discourse around AI in education, which shapes their baseline expectations before any instructor message. Analyses of public discourse and how platforms like YouTube frame ChatGPT use in education show that prevailing frames — hype, doom, or pragmatism — influence how learners and educators approach the technology.(How YouTube Frames ChatGPT Use in Education: An Epistemic Network Analysis with Supporting Multimodal Metadata)(A Longitudinal Analysis of Public Discourse on AI Ethics in Education Using Twitter Data) Effective framing by instructors often means deliberately countering or redirecting these ambient narratives.

Practical guidance

- **Position AI as a productive resource** by explicitly teaching *when* and *how* to use it, rather than banning or ignoring it — integrated framing beats both condemnation and laissez-faire.
- **Message expectations repeatedly and from every "site"** — syllabus, assignment prompts, Feedback, and peer norms should tell a consistent story so students don't invent their own rationalizations.
- **Channel anxiety into evaluation.** Frame uncertainty about accuracy as a reason to verify and revise, not as a reason to avoid or cheat.
- **Use honest, targeted messages** (e.g., inoculation and fallibility warnings) that build calibrated caution rather than blanket trust or distrust.
- **Sequence the tool to the phase of learning.** The 30-expert consensus report's central practical claim is an order: acquire ideas first without GenAI, then use it to strengthen and consolidate what has been learned, then prioritize one's own thinking when applying those ideas in new contexts (Kendeou, Greene & Nixon et al., 2026). Its advice for students is blunter: short-term performance gains short-cut the learning needed for long-term success.
- **Sell the purpose.** Connect AI use to durable learning and learner Learner Agency, and pair messages with the support that converts intent into take-up.

Common Misconceptions

"A clear policy tells students what the rules are, so framing is unnecessary." Policy text is not framing, and the gap shows in behavior: most students use generative AI, **many are unsure whether their own use complies**, and they lean on privately accessed tools rather than institutionally provided ones. A student who cannot tell whether they are compliant is not being communicated with, whatever the document says — which is why the page puts "say why, not just what" in its method.

"Publishing a policy and providing a licensed tool covers the institutional responsibility." Access and take-up are different outcomes, and this page exists because the second one is where the lever is. Structural

Guardrails change the environment automatically, but Scaffolding, literacy training and use policies only take hold when students are actually convinced of their point — that is the buy-in dependency the page names.

“Banning a tool removes the behaviour.” It relocates it to tools you cannot see. Students already prefer privately accessed tools over institutionally provided ones, so a prohibition pushes use out of the only environment where support, logging or guidance is possible. The framing task is to make the permitted behavior the attractive one, not to make the prohibited behavior harder to observe.

“Framing is persuasion, so it is more rhetoric than design.” The framing this page describes is paired with design: expectations stated clearly and repeatedly *while designing around students*. Messaging delivered instead of designed-for is the version that fails, because students read the difference between a stated commitment and an actual one.

Reducing AI Misuse

> **Reducing AI misuse** — the design, pedagogical, and policy levers that prevent students from substituting generative AI for their own cognitive work and instead steer them toward ethical, productive use. Effective approaches are sorted by impact rather than popularity, and the strongest evidence favors **structural levers** — tool Guardrails and assessment redesign — that change the environment so misuse is harder, regardless of a student's motivation, over **educative levers** that rely on building durable capacity and student buy-in.

Questions to Consider

- Students who outsource homework to AI can see their homework scores *rise* while their closed-book exam scores *fall*. Before you read, why might performance and learning diverge so sharply — and what does that gap suggest about what 'success' with AI actually means?
- The page ranks interventions by causal evidence and reach, and it places *structural* levers (tool guardrails, assessment redesign) above *educative* ones (teaching good practice) — precisely because structural levers work regardless of a student's motivation. Do you agree that changing the environment beats changing minds? What's the risk of relying on each?
- A guardrailed 'hint-not-answer' tutor eliminated the learning harm that an unguarded one caused, even though both seemed helpful. Think of a learning tool you've seen that gives answers too readily. Where's the line between a hint that scaffolds and an answer that substitutes — and can you state it before reading?
- The strongest fix includes assessment redesign: unassisted in-class exams, oral defenses, process artifacts, reasoning rewarded over surface fluency. How would you feel taking a course graded this way, and does that feeling tell you something about why this lever is both effective and unpopular?
- AI declaration frameworks that force students to map their use to cognitive stages (planning vs. content generation) shift emphasis from policing to professional practice. Do you think such reflection genuinely builds better judgment, or does it just teach students how to describe misuse more cleverly?
- Set a goal before reading: identify one concrete change in your own course or workflow that would make AI misuse harder, and one that would make productive use easier. Which of the page's tiers would each belong to?

Introduction

The concept rests on the evidence that AI misuse actively harms durable learning — the performance–learning gap documented in AI Misuse and Learning Harm — even while inflating immediate performance. Interventions therefore target the mechanisms of that harm: answer-copying, Cognitive Offloading, motivation erosion, and learning displacement. They are not mutually exclusive; a robust approach combines a structural floor with educative capacity-building.

The mechanism by which misuse forms now has a measured chain behind it. Guo and Dong (2026) surveyed 600 undergraduates and found perceived cognitive load predicting cognitive offloading at β = 0.844 in the low-monitoring group and β = 0.840 in the high one. Offloading then predicted overreliance on AI feedback at β = 0.396 and β = 0.506 respectively, with indirect effects of 0.335 [0.069, 0.611] and 0.426 [0.149, 0.648]. Load also predicted overreliance directly (β = 0.560 and 0.419), so offloading is a partial mediator, and the antecedent a structural lever can attack is the load itself.

Why structural levers matter most

Interventions can be sorted by **causal evidence × structural reach × scalability × Sustainability**. On this basis, the two *structural* levers rank highest because they work whether or not students choose the right behavior — they constrain the environment rather than depending on internal motivation. The *educative* levers are essential but only effective when students buy in, so they are treated as the second tier despite their conceptual promise. Coates, Croucher and Calderon (2025) push the structural argument up a level, treating governance rather than student behavior as the binding constraint and proposing a 130-item integrity indicator framework so that academic governors can see whether assessment is authentic, whether students are known individually by the teachers who assess them, and whether integrity features in induction and orientation. Their reforms target governance architectures, people, and technologies and resources, and they propose borrowing red teaming from cyber security to expose assessment vulnerabilities before students find them — a reminder that the structural floor is maintained by institutions that need both the information and the will to maintain it. The responsible-use literature itself rarely tests the chain this ranking assumes. Of 122 approach records drawn from 31 studies, 51 were both implemented and evaluated, mostly through self-report, and only four studies defined a boundary, designed an intervention around it and tested whether students' decisions aligned (Tie, Gil Ortega and Zhao (2026)).

Tier 1 — Directly proven to reduce learning harm

Guardrailed AI tool design ("hint-not-answer" Scaffolding). In the strongest causal finding in the knowledge base, a field RCT showed an unguarded ChatGPT-style tutor raised assisted practice performance **+48%** but reduced unassisted exam scores **−17%**, while a guardrailed tutor (hints instead of answers, plus teacher-authored problem information) eliminated the harm entirely. This mechanically prevents the answer-copying "crutch" behavior behind the damage. Activities include hint-not-answer tutoring, seeding prompts with correct solutions and common Misconceptions about AI, and requiring a student attempt before AI output is revealed.

Withholding the answer protects in-session without building the skill. Tuo et al. (2026) withheld the aggregate position in a multi-agent debate and cut switching to an incorrect AI position from 42–60.5% to 5.7–8.2%, but found no learning effect within the session (β = 0.03, p = 0.18) — the guardrail held while it was in place and left unaided judgment unmoved.

Assessment redesign (AI-resistant + unassisted measures). Because misuse harm is assessment-dependent — surfacing on proctored, closed-book, and unassisted measures while inflating ordinary graded coursework — changing what counts as achievement both deters misuse and surfaces it. Activities include unassisted in-class exams and oral defenses, requiring process artifacts (drafts, reflections, annotated reasoning), rewarding reasoning over surface fluency, and designating AI-free zones. Ivory et al. (2026) give the

process-artifact requirement a concrete instrument: mandated version histories and reproducible analysis documents, so a suspected submission can be inspected as a timeline of how the work developed, and the amount of fabricated material a student would have to generate rises far beyond what outsourcing saves them. Large-scale field evidence underscores this: Strömberg, Lei, & Wu (2026) found that homework outsourcing raised homework scores 18% while *lowering* closed-book exam scores 20% — exactly the signal that unassisted, proctored measures are designed to surface, and the study recommends weighting closed-book in-person assessment more heavily. Leaton Gray, Edsall and Parapadakis (2025) give the same logic its most explicit situational-crime-prevention statement, arguing that the failure belongs to assessments a model can answer convincingly rather than to students, and reporting a case in which 25 prevention techniques applied to an Australian business capstone — tracked student interactions, red-flag detection of too-expert work, random team reassignment, weekly in-class invigilated tests, takedown notices for course materials students had published — reportedly cut misconduct cases from 183 to 27 within a year. Their prescriptions are motivational rather than investigative: raise the perceived purpose of assessment, build Self-Efficacy, and increase the perceived social cost of cheating, with the authors warning that addressing only one or two of the three will fail, supported by five discipline-specific redesigns that turn timed problem-solving exams into open-book problem solving with a written reflection on the student's own process, summative essays into collaborative archival research projects, and portfolios into iterative peer-reviewed design processes.

The structural levers have an enforcement arm, and its evidence base is weaker than its reach suggests. Munoz et al. (2026) coded 1,162 generative-AI misconduct cases and found that the evidence most often cited at the point of allegation — detector output, similarity reports, AI-typical content patterns — carried the weakest probative value, while admissions, observed exam behavior and independently verified fabricated references were the strongest. Because institutional procedures set no minimum evidentiary threshold, evidence quality bore no reliable relationship to case outcomes, and students whose cases rested on thin evidence had recourse mainly to appeals. Wright (2026) shows a second cost of the same imprecision: prohibitions written around "generative AI" rather than around function capture tools that merely convert the format of work a student has already authored. Transcription-only use can therefore be sanctioned as misconduct — an over-inclusion that falls hardest on disabled and equity-exposed Learners and does nothing for validity. Harerimana, Mtshali and Mchunu (2026) add that remote proctoring, the most widely adopted integrity control, rests its deterrence case on how students say they feel rather than on reduced misconduct, and imposes anxiety, concentration loss and infrastructure-related exclusion that is not shown to be answered by lower misuse. Li (2026) adds the rule-design dimension: because the same interface performs permitted language editing and prohibited substantive drafting, undifferentiated GenAI rules impose cohort-skewed compliance burdens on students who use English as an additional language. The more defensible prevention is a purpose-based support-substitution boundary anchored in the assessment construct, with calibrated disclosure, proportionality staged across threshold, evidentiary and sanction decisions, and design levers — staged submissions, short construct-aligned oral verification, critique-based questions — doing the work detection cannot. The grader itself belongs on that surface. Humble's (2026) red-team work shows what an uploaded file can do to an automated grader: two of five indirect prompt-injection strategies carried inside it lifted a failing essay to a pass without detection, at reported success rates of 100% and 94%. Where AI tools grade student work, human review, clearer separation of instructions from submitted content and resilience testing belong in the structural floor rather than in an optional tier.

Tier 2 — Strong framework support, high potential

Scaffolded use sequences: think first, AI second, reflect third. Eight design principles for integrating LLMs without displacing Critical Thinking: preserve cognitive friction, position AI as a provisional thinking partner rather than an authority, embed evaluation checkpoints, require metacognitive journaling and prompt logs, and balance AI-mediated with AI-free phases. Correlational evidence (independent work before AI produces stronger outputs) is strong; it is the pedagogically complete version of Tier 1.

AI literacy and prompting literacy with deliberate practice and immediate Feedback. A K-12 module using scenario-based prompt practice with an Large Language Models (LLMs) auto-grader improved actual prompting skills and raised confidence in using AI for learning **+10.4%**, with 87% reporting they learned how to use AI responsibly. Demonstrated skill gains; the open question is whether these convert into downstream learning outcomes. It also addresses the equity gap in prior AI access.

Structured AI-use declaration frameworks. Replacing generic "I used AI" checkboxes with domain-specific declarations that map use to cognitive stages (structural planning vs. content generation) forces reflection on the learning process and clarifies the boundary between acceptable assistance and misconduct, shifting the emphasis from policing to professional practice.

Educative levers look different again once integrity is treated as a practice to be taught rather than a rule to be enforced. Sharma (2026) argues that detection- and verification-based integrity regimes are misaligned with GenAI-augmented work, and reframes integrity as pedagogical practice enacted through evaluative judgment. That judgment is the learner's capacity to weigh options, justify academic choices and take responsibility under uncertainty, made visible through artifacts such as annotated decision trails, documented verification, oral defense and draft-to-draft version histories, with detection demoted to one supplementary layer rather than the primary infrastructure. Mulisa and Mezgebu (2026) find the same opening from the students' side: across 27 interviews at an Ethiopian university, use was near-universal, most participants credited GenAI with raising their achievement, and the sharpest complaint ran the other way — AI users scoring above diligent independent workers, which participants described as demotivating. The authors conclude that students' beliefs predict ethical use more strongly than institutional rules do, so awareness, clear policy and assessment redesign have to arrive together — which is the page's educative tier stated as a condition: capacity-building changes behavior only through student buy-in accompanied by a structural floor. Ji's (2026) scoping review of 38 studies of student voices supplies the field-level version of the same conclusion. The reviewed studies converge on a shift from retrospective detection to proactive ethical reasoning, on teaching AI ethics and AI-giarism in the curriculum rather than in one-off literacy sessions, and on detailed guidelines co-created by leaders, faculty and students. Unclear guidance, they note, is read as tacit permission rather than as caution. Ji's own reading is that ownership and moral reasoning motivate students more than fear of punishment, and that students are neither passive recipients of GenAI nor culprits without moral constraint but moral agents working a gray zone — this tier's premise, stated as a finding.

Tier 3 — Promising, lower direct causal evidence

Metacognitive and Self-Assessment interventions. Reflective journals, prompt logs, and calibration training rebuild the "absent cognitive baseline" of AI-native students who cannot locate their own cognitive boundary because AI-generated fluency masks it. Conceptually central but not yet causally tested.

Motivation redesign. Because AI availability erodes autonomous motivation ("why put in the effort?"), restructuring tasks around goals AI cannot fulfill and around learner agency directly targets the persistence erosion that compounds the direct harm.

Critical AI literacy. A power-knowledge framing that teaches learners to interrogate, challenge, and participate in AI governance rather than consume it. Long-term, equity-oriented, and structural in its ambitions, though its learning effects are largely untested.

Recognizing sycophancy to prevent uncritical acceptance. Because sycophantic AI validates rather than challenges the user, it is a direct misuse vector: students who receive affirming agreement for incorrect thinking are encouraged to substitute AI for their own cognitive work. Contextual sycophancy shows AI literacy and prompting training reduce but do not eliminate the error loop, so misuse prevention must pair educative recognition training with system-level corrective-friction design (see Tier 1 guardrails).

- **Productive friction and pedagogical function.** The Sydney rapid review argues GenAI undermines learning when it lets students bypass the cognitive/metacognitive friction needed to learn, and that purposefully designed tools introduce *productive friction* (withholding answers, prompting explanation). It distinguishes four pedagogical functions — learning *from*, *with*, *about*, or *by shaping* GenAI — each with different demands on agency and assessment.(Young people, learning, and generative AI: A rapid literature review and implications for PreK-12 education)

Common Misconceptions

"Teaching students about the risks is the main lever against misuse." It is the lever that depends on the student cooperating, which is why it ranks below the structural ones here. Guardrails and assessment redesign work whether or not a student chooses the right behavior; educative approaches work only with buy-in. The distinction is not moral but mechanical — a changed environment constrains the behavior directly, while a changed belief must survive the night before the deadline.

"If a guardrail holds during the session, the learning is secured." Holding and teaching are separate outcomes, and the corpus contains a clean double result. Withholding the aggregate position in a multi-agent debate cut students' switching to an incorrect AI position from 42–60.5% down to 5.7–8.2% — a large protective effect — yet produced **no learning effect within the session** ($\beta = 0.03$, $p = 0.18$). The rail did its job as a rail and did not become instruction. Designing for misuse prevention is not the same as designing for learning.

"Detecting misuse and punishing it is a prevention strategy." Prevention has to cover the grader itself. Humble's (2026) red-team evaluation found that two of five indirect prompt-injection strategies embedded in a submission file raised a failing essay's score. A pipeline that detects student misuse while trusting unexamined submission content is defended on one side only.

"Misuse is a student-motivation problem." Coates, Croucher and Calderon (2025) push the binding constraint up a level, treating governance rather than student behavior as the thing to change and proposing a 130-item integrity indicator framework. And the learning harm is measurable at scale: Strömberg, Lei and Wu (2026) found homework outsourcing raised homework scores 18% while *lowering* closed-book exam scores 20% — a design failure that shows up in exactly the gap this page is about.

Implementation Guidance by Role

For instructors and course teams

- Start with the assessment, not the policy text. Ask of every graded task whether the unaided version would show what you intend to certify, and fix the task first — it is the lever that does not require student consent.
- Adopt hint-not-answer tooling where an AI tutor is available, since the field RCT on guarded versus unguarded tutoring is the strongest causal evidence in the area.
- Sanity-check that your own grading pipeline resists injected instructions in submitted files before treating student misuse as the only threat.
- Treat AI-permitted and unassisted performance as two different measurements; the 18%/20% split above is invisible unless you collect both.

For developers

- Build the restriction into the interface rather than into a warning. A tutor that can produce the finished answer will, under deadline pressure, produce the finished answer.
- Do not infer learning from compliance with the guardrail. The debate result shows behavior held while learning measures stayed flat, so instrument outcomes separately from interactions.
- Surface misuse signals to instructors as diagnostics rather than as verdicts, since governance framing in the evidence sits above individual student behavior.

For administrators and policymakers

- Put the binding constraint where the evidence puts it. Indicators and governance structures address the environment; exhortation to students addresses the person least able to change institutional design.

Academic Integrity

> **Academic integrity** — the ethical framework governing honest academic work in the age of AI. The knowledge base documents how the concept has been reframed by generative AI: from a problem of detecting dishonest output to a design problem of making honest work visible, verifiable, and worth producing. Academic integrity research in this space has evolved from detection-focused approaches toward fundamental assessment redesign, pedagogy-led governance, and teaching students how to use AI well rather than merely policing whether they do.

Questions to Consider

- Think of the last time you heard ‘AI cheating’ discussed. Was the conversation about catching students or about designing assignments students would want to do honestly? Which emphasis feels more familiar to you, and why?
- A polished, plausible piece of work can now be generated in seconds. If you can no longer judge a student’s capability by the product they hand in, what would you need to see or hear to feel confident they actually learned it?
- Research finds students often rationalize AI use (‘copying AI text is victimless’) rather than misusing it out of malice. What assumptions about students’ motives does a purely punitive integrity policy make — and what might those assumptions get wrong?
- One line of research treats students’ AI use as a coordination problem: behavior shifts when peer expectations and assessment incentives change, not when rules are restated. What peer or design factors in your own context might be quietly shaping whether AI use is honest?
- Studies show fear of penalty drives students to hide AI use, and that transparent students can even draw suspicion. If you were designing an ‘AI use disclosure’ form, what would make a student actually want to fill it out truthfully?
- The same institutional AI policy is interpreted differently by students across cultures — culture, not policy wording, drives what feels wrong. How should an integrity policy be communicated to a culturally diverse cohort so expectations are actually understood?

Introduction

The arrival of generative AI has not created the need for academic integrity — it has made weaknesses in existing approaches harder to ignore. A polished, plausible product can now be generated in seconds, so **product resemblance is an increasingly unreliable signal of capability**. This shifts the integrity question from *“can we catch AI use?”* to *“can our assessments still warrant the inferences we draw about student learning?”*

The evolution from detection to redesign

- **Detection skepticism:** AI Detection research and institutional analyses increasingly find that AI detection tools are unreliable and procedurally unfair. LLM text detection faces fundamental limitations. Fully AI-generated submissions can pass through live examination systems largely undetected, and experienced markers do not reliably spot GenAI-authored work. Detection, at best, is a limited, situational tool — not a strategy of first resort. The volume it is nonetheless asked to handle is far from marginal: a six-year analysis of a large-enrollment CS2 course found 45.7% of Spring 2026 students flagged for patterns consistent with LLM-assisted coding (Racovan et al. (2026)).
- **Detection's narrow margin, and cheating as planned behavior:** Leaton Gray, Edsall and Parapadakis (2025) assemble the case that AI amplifies a vulnerability the sector already had. AI-generated text has passed as human-authored in up to 80% of cases, while the evidence they cite puts machine detection at about 80% against 78.4% for human reviewers, too narrow a margin to carry a misconduct finding. Their motivational analysis is the more distinctive contribution: working from Ajzen's Theory of Planned Behavior and Bandura's self-efficacy theory, they report Krou et al.'s (2021) meta-analysis finding that Self-Efficacy correlates negatively with cheating while actual ability does not correlate inversely with it at all. A capable, confident student who reads an assessment as unfair may therefore cheat to regain control. The conclusion follows the same inversion this page documents elsewhere — an assessment a model can answer convincingly is an intellectually trivial assessment, and the failure belongs to the assessment rather than to the student.
- **Assessment redesign:** Authentic Assessment, beyond-detection approaches, and the AI Assessment Scale shift the focus from catching AI use to designing assessments where AI use is either irrelevant, transparent, or required to demonstrate a specific capability.
- **Structural vulnerability of grading:** Chan et al. provide a concrete case study of how current grading is structurally exposed to AI-mediated dishonesty. In a biology department, instructors perceived only in-person proctored exams as minimally vulnerable; outside-of-class assignments were seen as highly vulnerable, leaving about a third of a student's grade highly vulnerable and 80% at least somewhat vulnerable. This frames the integrity problem as partly a *grading-design* problem, motivating rebalancing toward proctored or in-class assessment and authentic assessment designs that are harder to outsource. Ivory et al. (2026) supply the discipline-level counterpart with a whole three-year psychology program: 36 of 40 assessments across 16 types produced passable content at minimum effort, and the four that failed were those requiring presence, visual media, or the student's own dataset. Their reading of *why* it passes is the part that generalizes — marking that rewards fluent structure and good-faith use of the right analysis condones fabricated values and hallucinated references, so the pass boundary rather than detection decides whether AI output is graded as achievement, and the assessment vulnerability "cannot be blamed solely upon student usage."
- **The submission as an attack surface: prompt injection against AI grading.** Humble (2026) red-teams an everyday grading workflow and shows that a student submission can carry hidden instructions that change the grade an AI tool produces: two of five indirect injection strategies

embedded in the submission file raised a failing essay to a pass with no visible warning to the user, at reported attack success rates of 100% (9/9) and 94% (17/18), both combining instruction manipulation, role-playing and obfuscation across docx, pdf and htm formats. The most basic attack failed completely, and its refusal was silent — the tool disabled the chat without reporting the attempt — while a single detected injection produced a reassurance that the tool would grade "only according to the official assignment instructions" before six further runs of the same file raised the grade anyway. The integrity consequence runs in both directions: a grade raised by a hidden instruction carries no validity claim, the same technique could be used to degrade a submission with no durable trace in the output, and the human marker is left as the only real check on manipulation designed not to be visible.

- **Validity as the organizing frame:** Assessment Validity reframes integrity as an evidential problem. Authentic assessment research introduces **construct substitution** — an AI-generated product is attributed to the student, so the assessment infers the tool's capability rather than the student's. The evidential question survives any AI policy: whether use is prohibited, permitted, or required, the assessment must still generate evidence warranting the inference being drawn.
- **Variation-at-scale as a no-surveillance integrity mechanism:** VARIA (Lee 2026) Benchmark the premise behind AI-Integrated Authentic Assessment (AIAA) — replacing surveillance-based proctoring with per-student task variation so copying is structurally useless. The integrity guarantee is conditional on LLMs generating variants that are surface-distinct and construct-equivalent; VARIA's 600-variant pilot finds frontier models satisfy this only at the margin (joint score 0.81–0.88) while non-frontier models collapse (0.50–0.55), so "variation-at-scale cannot be solved by prompting alone." This gives the detection-vs-redesign debate an empirical, falsifiable check: the no-surveillance promise of authentic, task-varied assessment now depends on a measured (and still narrow) generation capability rather than an assumed one.
- **Authenticating student reflection against GenAI:** Kadel et al. (2026) argue that traditional reflection models can no longer authenticate student reflection once GenAI can author reflective prose, and embed integrity directly inside a reflection model — the 5P framework's Pitfalls stage explicitly handles plagiarism, hallucination, and over-reliance, while its Process and Product stages require documenting prompts and validating outputs so that Learners' own reasoning is distinguishable from AI-generated contributions.
- **Policy development:** Institutional AI policies and Educational AI Policy research examine how universities develop and communicate integrity expectations — and why abstract policy statements so often fail.
- **Integrity as a governance problem, not a detection problem.** Coates, Croucher and Calderon (2025) relocate the binding constraint from student behavior to academic AI Governance, which they call resilient yet "not well positioned or poised" to meet GenAI-related threats to the authentication of student assessment. Their answer is an integrity indicator framework of 130 items across eight dimensions, running from Designing (19 items) to Improving (6), and comprising governance questions rather than psychometric scales — whether the institution's top board receives assessment-quality updates, what percentage of assessment resembles relevant and meaningful problems, what percentage of students are known individually by the teachers who

assess them. It was developed through a multiyear research review, five Australian university case studies, prototyping, expert confirmation with 60 invited experts across six world regions and quantitative piloting, and it is paired with reforms to governance architectures, people, and technologies and resources that the authors expect to pay out only under external pressure from AI Regulation in Education, benchmarking and cross-institutional competition; they present the framework as formative and call for psychometric validation before it is used for comparison or measurement.

- **What the documents actually say: integrity dominates institutional AI policy.** Eldredge et al. (2026) analyzed the AI policy and guidance documents of all 48 CAHIIM-accredited health informatics and health information management master's programs in the US: 40 (83%) had at least one qualifying document, and those documents framed AI overwhelmingly as a matter of preventing student misuse in coursework, centering academic integrity and acceptable use. Academic integrity was by far the most frequent keyword (n = 139, ahead of citation at 59, assessment at 50, and plagiarism at 38), while privacy, intellectual property, and regulatory themes were present but less common (HIPAA n = 5, FERPA n = 11, IRB guidance n = 8). Topic modeling over the same corpus returned four themes, the first being academic integrity and appropriate AI use, alongside generative AI in teaching, AI and data-tool use in research, and student engagement with conversational AI systems. The evidential value for this page is the quantification: integrity-centered framing is not just the rhetorical default of institutional AI policy, it is empirically the dominant content of it. The authors' sharpest observation is about where that attention stops, noting that comparatively little guidance covers AI use in applied learning, research, and simulated environments, where curricular and data-governance concerns intersect, so the documents govern coursework while the settings the degree is preparing students for go largely unaddressed.
- **Integrity framing is giving way to task-based regulation:** Chirikov's (2026) longitudinal study of 31,000+ course syllabi shows instructors' AI policies shifting away from a purely integrity-based frame: academic-integrity mentions in syllabi fell from 63% (Spring 2023) to 49% (Fall 2025), while references to AI's impact on learning rose from 1% to 29%. Instructors increasingly regulate AI **by task type** — restricting it for drafting/reasoning (where AI would displace learning) and permitting it for editing/proofreading and study support — rather than applying a blanket integrity prohibition. This reframes integrity policy as a task-level design decision rather than a binary rule.
- **Machine resistance as prevention, not detection.** Perturbing the document itself — character, word and line spacing, opacity jitter, stripe overlays and image noise, plus decision-based adversarial attacks — raises the effort needed for low-effort LLM misuse at the source while measuring the same knowledge (Salaun et al. (2026)). Manual transcription remains possible, and adversarial attacks protect only selected lines, leaving whole-document character error under 8.44%.
- **Teamwork with per-member verification, in place of detection.** Issa and Hall (2024) ran a postgraduate Business Project Management unit for five semesters on the premise that an instructor can establish authorship from the process rather than from the artifact. The 12-week team plan carried 40% of the unit, each team met the lecturer for 30 minutes to review its work

and organizational breakdown structures, and each member was asked whether their contribution was original. Each student also wrote a peer-reflective form per teammate and a self-reflective form. Unit evaluation items scored 89% to 100% against university averages of 80% to 86%, and the project-plan average moved from 27/40 to 31/40. Its claim that misconduct and extension requests fell “dramatically” carries no counts, and a new lecturer arrived in the same semester as the redesign, so read this as a workable design, not as measured evidence that AI use fell.

The misconduct procedure and its evidentiary collapse

The enforcement machinery that sits on top of integrity policy is itself a design decision, and generative AI has dismantled its evidentiary foundation. Teichmann (2026) argues that the misconduct procedure universities imported from plagiarism assumes prohibited use can be detected and proved — a premise the technology dissolves. Unlike text-matching software, which points to a copied source, an AI-text classifier identifies no source (none exists); it outputs a probabilistic judgment about style that degrades under paraphrase, systematically mislabels non-native English writing, and cannot be explained or cross-examined, while skilled or lightly edited use leaves no trace at all. Persisting anyway reverses the burden of proof (the student is asked to prove a negative), strains every element of procedural justice, and lands the harm of false accusation hardest on the already disadvantaged. The proposed remedy is twofold: an evidentiary standard under which a detector score alone never grounds a finding, with graduated, education-first responses, and a shift of institutional effort into validity-centered and authentic assessment design — the answer to undetectable AI being better assessment rather than better surveillance. The limit case has no machinery at all: Isley, Gaebler and Goel (2026) document a US public policy master’s program that prohibited generative AI assistance in a signed attestation and screened no submissions, where 56.1% of 2025 applicants submitted at least one essay a commercial detector classified as primarily AI-written and each flagged essay was associated with a 1.5 percentage point lower admission probability ($p < .01$), rising to 2.6 points ($p < .001$) once essay quality was held constant. With no detection, adjudication or enforcement step between the rule and the outcome, the penalty was delivered entirely through admissions readers’ unwritten judgment — prohibition plus unaided reader judgment reproducing the discretionary, unexplained sanction a fair procedure exists to prevent.

Munoz et al. (2026) supply the empirical counterpart by coding every GenAI misconduct case at one regional Australian university over three years: 1,162 cases carrying 1,855 evidence items, each rated for relevance, credibility and inferential force. Detector output was the evidence most reached for and least able to bear weight — Turnitin or similarity reports carried 100% Weak inferential force and standalone detector output 100% Low credibility, and detector evidence fell to 0.5% of items by 2025 as institutions absorbed what it could not prove — while the strongest evidence types were those that do not rest on probabilistic text classification: student admissions, observed prohibited exam behavior, and independently verified fabricated references, which were the largest structural shift at 22.3% of items. Their sharpest criticism is structural rather than evidentiary, since “there is no requirement for investigators to assess the probative quality of evidence before progressing an allegation, no minimum evidentiary threshold at any stage of the pipeline,” so evidence quality bore no reliable relationship to case outcomes. They also record how policy caught up with practice: the assessment policy in force through 2024 said nothing about AI, and from January 2025 a revised policy permitted approved authenticity software while prohibiting the upload of student work to third-party AI-detection tools.

A second failure is one of scope rather than proof. Wright (2026) shows that prohibitions written at the level of platform identity rather than function capture non-generative format conversion — speech-to-text transcription, OCR, plain text to LATEX — alongside the generative drafting they mean to bar, even though the peer-reviewed computer science literature treats recognition and generation as distinct operations. The cost lands unevenly: students with conditions affecting fine motor control, handwriting legibility or typing accuracy have relied on exactly those tools, and as standalone voice-to-text products are discontinued or degraded, AI-powered transcription is filling the functional gap, so an over-inclusive rule removes a primary means of producing legible work, making the dispute an Accessibility and equity one before it is an integrity one. Wright's remedy is a function-based definition of generative AI plus four operational criteria — fidelity, non-augmentation, traceability and attestation — that give a student a structured route to rebut a transcription-only allegation while leaving the burden of proof with the institution.

Detection's evidentiary problem is also a validity problem. Because AI assistance is iterative and interwoven with drafting rather than outsourced wholesale, authorship and ownership of meaning come apart, and a sound submitted product may not establish that the student exercised the judgment the task was meant to target. Detector performance varies across tasks, disciplines and model versions, and disclosed or suspected AI use can act as a biasing cue for markers, so a detection response adds construct-irrelevant variance rather than removing it. Where integrity debates ask who produced the words, a validity account asks what claim about the student the performance warrants.

Integrity rules are applied to a phenomenon they do not model. Hong et al. (2026) locate the problem in answerability rather than in how much of the text a machine wrote: an authorship legitimation deficit appears when a designation outruns the grounds the person can offer for the contribution they made. A rule that measures the proportion of generated text therefore cannot see the mismatch it means to catch, and a disclosure that AI was used says nothing about what the human contributed.

The rationalization problem

Students do not generally misuse AI out of malice; they rationalize it. Interview research identifies at least **five disconnect sites** where students' interpretation of AI policy diverges from faculty intent, and a taxonomy of **20+ distinct rationalizations** — from "copying AI text is victimless" to "text reflecting my beliefs is my own writing." These rationalizations are ad hoc, post hoc, and internally inconsistent, and they describe a "steep, ethical slippery slope" on which students slide far outside pedagogical goals. This is why student misconceptions about AI are the upstream cause of integrity violations, and why integrity education must address ethical reasoning, not just technical skill.

Ji's (2026) scoping review of 38 empirical studies of student voices supplies the synthesis this section rests on. Its four themes are ambiguity (generating a whole task reads as cheating, grammar checking and brainstorming are largely acceptable, and paraphrasing, outlining and translation sit in a gray area), ethical Learner Agency in which students build personal rules in a guidance vacuum they read as a silent approval of their actions, the gap between ethical awareness and practice, and diversity by gender, level, discipline and culture. The awareness-practice gap is the rationalization problem measured at scale: Huang et al.'s Ethical Dissonance Index sorted 522 Chinese students into four clusters, one of which frequently did what it viewed as illegitimate, and Ofem et al.'s structural-equation modeling of 4,679 Nigerian students found that positive perceptions of ChatGPT predicted dishonest use while positive integrity attitudes acted as a

significant negative mediator. Ji reads students as neither passive recipients of GenAI nor culprits without moral constraint but active agents navigating an ethical gray zone, which is why the reviewed studies converge on co-created, educative and context-sensitive responses rather than punitive ones.

Why policy alone fails: the coordination problem

A coordination-game framework provides a mechanism-level account of why policy pronouncements rarely change behavior: students' AI use is a **coordination problem**, where individual choices depend on peer expectations and assessment design. The model's key finding is **non-linear threshold dynamics** — small, well-calibrated changes to reflective-assessment incentives can trigger rapid cohort-wide shifts toward responsible use, while weak or misaligned incentives let opportunistic practice persist. In practical terms, modest redesign (e.g., requiring students to reflect on their AI interactions) can have disproportionate effects where abstract rules have none.

Peer accountability does not always point toward integrity, as Chen and Zou (2026) found in graded group assessment: seven of fifteen student groups deliberately reduced their GenAI use partly to avoid free-riding on groupmates, since group consequences were shared rather than self-contained, yet in five groups a permissive collective climate — "everyone in my group is using GenAI" — lowered the perceived risk of misuse and inverted the very accountability mechanism group work is meant to create. The same study found students reframing originality as faithfulness to the understanding their classmates built together, and its practical recommendation follows directly: make the negotiation of acceptable AI use an explicit, documented, and assessable outcome rather than leaving the norm to emerge from peer pressure or perceived risk.

Policy inconsistency across the institution produced exactly the guessing the coordination account predicts. Nine of the eleven interviewees in Zou et al. (2026) framed their own course's explicit permission to use generative AI as a possible "trap" — a lure to identify students who could not resist — even though the policy was open and written into the assessment guidelines; students generalized from bans and warnings encountered elsewhere rather than reading their own course's rules on their own terms. The authors' conclusion follows the mechanism rather than the wording: per-course clarity was not enough, and program- or institution-level consistency is needed so that students stop inferring intent from the surrounding culture.

Identical conduct, different verdicts - and disclosure that changes nothing. Poudyal (2026) applied 15 standardized vignettes to the policy environments of 20 Australian universities and produced 300 classifications: 120 (40.0%) clearly prohibited, 56 (18.7%) indeterminate, and none clearly permitted, while binding instruments were silent on generative AI in 100 combinations that guidance resolved in 88. Disclosure did not determine outcomes - the same disclosure status produced different classifications depending on permission rules and task instructions, and the disclosure field recorded 117 satisfied requirements and 80 false declarations.

Procedures matter as much as policies, and their evidentiary basis has collapsed for AI. Teichmann (2026) argues that the misconduct procedure universities imported from plagiarism rests on a premise generative AI dismantled: that prohibited use can be detected and proved. Unlike text-matching software, which can point to a copied source, AI-text classifiers identify no source because none exists — they output a probabilistic judgment about style that degrades under paraphrase, misclassifies non-native speakers systematically, and cannot be explained or cross-examined, while skilled or lightly edited use leaves no trace at all. Persisting

anyway reverses the burden of proof (the student is asked to prove a negative), strains every element of procedural justice, and lands the harm of false accusation hardest on the already disadvantaged. The proposed remedy is twofold: publish an evidentiary standard under which detector output alone never grounds a finding, with graduated education-first responses, and move institutional effort into validity-centered and authentic assessment design. Mohamed and Temimi (2026) supply the mechanism-level counterpart from the student's side: because each assessment environment makes some response most attractive, prohibition leaves concealment attractive when verification is thin, monitoring makes hidden use costlier without making disclosure safe, and only redesign — lowering the payoff from outsourcing while raising the value of visible reasoning — moves students toward responsible use. Their sharpest result is that deterrence runs through a detector's discrimination between hidden use and legitimate work rather than its catch rate, so when false positives rise faster than true positives, stronger monitoring can make concealment relatively more attractive.

- **Integrity duty can be rewritten as individual competence.** Across 366 GenAI higher-education abstracts, the word integrity appears 461 times but only 6 of 166 obligation expressions name students, so verification and disclosure surface as skills students are expected to have rather than obligations institutions enforce (Poudyal, 2026).
- **How prescriptive an integrity policy is does not reveal how exposed the assessment is.** Auditing 15,587 unit records, Villanueva (2026) found universities with institution-wide reform mandates and those with broad frameworks spread across the same range of assessment exposure - the empirical counterpart to the coordination-game account of why pronouncements rarely change behavior.

The socio-emotional dimension

Integrity enforcement has a neglected emotional cost. Shame-and-guilt research with students shows these emotions regulate when and how AI use becomes visible, producing **hiding behaviors and selective disclosure** — and that they coexist with continued use, creating cycles of reduced agency and moral tension rather than behavior change. That is why the norms around AI use regulate visibility more effectively than they regulate use. Students even describe their AI use in language of addiction. The implication: detection-heavy, surveillance-oriented policy risks **driving misuse underground** rather than addressing it, undermining the candid negotiation that productive use requires.

The obverse of hiding is declining, and it carries its own emotional cost. Among the 85 student teachers Zou et al. (2026) surveyed under an assessment policy that explicitly permitted generative AI, 62.4% (53) chose not to use it at all, and the adopters' use was shallow and corrective — proofreading (43.8%) and clarity checks (34.4%) far outnumbered text generation (18.8%) and brainstorming (12.5%). Fear of wrongful accusation, not technical difficulty, did much of the work: 41.5% of non-adopters named it, against 13.2% citing missing knowledge or skills, while 77.4% framed non-use simply as a preference for working alone. When a permissive policy is read as a trap, the safe response is refusing the offer — which costs the institution the AI-integrated work it was trying to invite.

AI use disclosure statements

AI use and disclosure statements are the concrete mechanism through which integrity expectations are operationalized — and the research shows they often fail when treated as neutral compliance forms. Gonsalves (2025) found 74% of students failed to declare AI use on a mandatory coursework coversheet, driven by fear of penalties, guideline ambiguity, inconsistent enforcement, and peer norms. Kirsanov et al. (2026) and Vetter et al. (2026) confirm that fear of retribution and unclear policy chill disclosure — and that transparent students can even draw suspicion. Chang et al. (2026) reframe disclosure as a Help-Seeking/self-regulation behavior that anxiety redirects toward peers. The collective lesson: disclosure policies must address the affective and social barriers, be clear and consistent, and treat disclosure as formative pedagogy rather than surveillance. **Luo & Dawson (2026)** add the teacher-side of the equation: teachers' grading of GenAI-assisted work is driven by value judgments about student honesty, diligence, and trust, and many teachers penalize (or are tempted to penalize) students who disclose GenAI use — even when the work quality is strong. This is the "two-way transparency" problem: students are expected to declare use, but teachers rarely clarify how that declaration will affect grades, so honest disclosure can carry an unstated grading penalty. The study grounds the disclosure problem in the value-laden reality of teacher grading and argues that transparency must run both directions.

Students' own reports quantify how badly that message is landing. In a survey of 504 sociology undergraduates, 81 percent said their instructors or teaching assistants had given guidance on AI use, yet only 46 percent called those instructions very clear; 19 percent reported receiving no guidance at all and the rest described it as at best somewhat clear (Kuznetsov, Sheely & Baker, 2026). Fear of committing an academic offense was the second most common concern students raised (28 percent) — a cost imposed by ambiguity rather than by enforcement, since only 3 percent reported using GenAI to generate assignment text and 2 percent to produce a full draft. The practical implication is that clarity of communication is itself an integrity mechanism, and that a student who cannot tell what is permitted bears a risk the institution never intended to impose.

Course-level permission does not resolve the disclosure dilemma either. In Zou et al.'s (2026) study of 85 student teachers whose assessments explicitly permitted generative AI, self-declarations totaled 28 users against 32 in the anonymous survey, and the two sources disagreed in opposite directions by course — Course A recorded 14 survey users but only 8 declarations, while Course C reversed the pattern (8 survey, 12 declarations). The authors read the divergence as graded consequences shaping what students were willing to make visible, adding student-teacher evidence that a declaration system measures disclosure behavior as much as it measures use.

Cultural and contextual variation

Policy text does not equal policy perception. Cross-national research found that, despite functionally identical institutional policies, students at different universities rated the same AI-assisted practices differently — **culture, not policy wording, drove perceived wrongness**. Policy harmonization does not produce perception harmonization, so culturally diverse cohorts interpret the same rules differently, an equity concern for enforcement and grading that argues for scenario-based clarification over abstract rule statements.

Language background rather than culture is a second axis of variation. Li (2026) argues that because the same interface performs permitted language editing and prohibited substantive drafting, integrity rules treating GenAI as one category of unauthorized assistance convert linguistic disadvantage into integrity risk: an outright ban removes a scalable form of language support, a permit-but-disclose regime loads compliance work onto EAL students whose use is more frequent and iterative, and prohibitions on editing beyond minor changes concentrate suspicion on writers whose fluency has shifted most. The boundary Li proposes is purpose-based rather than tool-based — permitted support adds no new ideas, no new sources and no material re-ordering of analysis, while substitution creates or materially reshapes the intellectual work being evaluated — and it is anchored in the assessment construct because rubrics that award marks for fluency and idiomatic expression introduce construct-irrelevant variance for EAL writers (Assessment Validity). The framework demotes detector output to a triage signal that rarely constitutes proof, preferring triangulation through staged submissions, draft histories, verifiable source trails and a brief construct-aligned conversation, and it calibrates disclosure so that routine support does not carry compliance costs exceeding those borne by monolingual peers.

From policing to pedagogy

The knowledge base documents a paradigm shift: from AI as an integrity threat to be policed, to AI as a tool whose appropriate use must be taught. This is the ethical dimension of AI Literacy and is embodied in practical design:

- **Task-specific AI-use declarations:** Domain-specific declaration frameworks replace generic "I used AI" checkboxes with structured declarations mapping use to cognitive stages (e.g., structural planning vs. content generation), forcing reflection and shifting focus from policing to professional practice.
- **Process-transparent assessment:** architectures such as cognitive stewardship, staged submissions, oral defenses, and the AI Viva (a conversational agent probing whether students understand their submissions) make human judgment, verification, and responsibility visible. Miles, Haber-Curran and Arar (2026) push the same logic down to the prompt itself: their sample rubric grades iterative refinement, critical interpretation of output, and reflective revision, so what is assessed is the student's engagement with the tool rather than the artifact it produced, and they argue that teaching students only to optimize output leaves the ethical and epistemological dimensions of use untouched.
- **Reducing misuse:** integrity sits alongside AI Misuse and Learning Harm (the learning cost of misuse) and Reducing AI Misuse (the interventions that prevent it), tying honesty to genuine learning rather than rule-following.
- **Transparency as an integrity strategy, not just a courtesy:** McCorkle's (2025) design case treats the *rationale* for each allowed or unallowed GenAI use as the integrity mechanism itself. Students interviewed after ignoring a prohibition policy explained that they did not see themselves as behaving dishonestly, which reframes the failure as ambiguity rather than noncompliance — so the redesign answered it by justifying every restriction with the specific Assessment it protects, and by designing for McCabe's "20-60-20" persuadable middle rather than the determined few.

The case also names the equity cost of vague policy: expectations that are unclear and uneven across instructors are what convert policy failure into disciplinary action (Equity).

- **Design, not detection: the Bochum case.** The Ruhr University Bochum redesign of introductory nuclear and particle physics (Mikhasenko et al., 2026) linked its AI policy to a practical integrity failure rather than to detection: because tutorial problems were disclosed in advance, some students prepared AI-generated solutions and copied them onto the blackboard without engaging in the intended reasoning. The authors treat this as a design problem — moving tutorial problems to prepared in-class discussion and making a written exam the grade determinant — rather than a policing problem, while explicitly permitting AI in study, explaining why verification is the student's responsibility, and noting that open-ended AI-permitted homework also raised dependence, uneven access to paid models, and teaching-assistant workload.

The clearest statement of the pedagogical inversion comes from El Khoury and Ma (2026), who argue that reform starting from suspicion narrows the educational imagination to control, compliance and surveillance, and that integrity should be a **consequence** of assessment designed for engagement rather than its starting point. Their supporting observation is a mechanism already visible elsewhere in this knowledge base: disengagement is one of the conditions under which dishonesty becomes more likely, so agendas that stress-test assessments or constrain AI use without addressing engagement leave part of the problem untouched.

Students outside Anglophone higher education describe the same tension in their own terms. Mulisa and Mezgebu (2026) interviewed 27 undergraduates at an Ethiopian university and found the student body divided against itself: almost all used GenAI or watched peers use it, most credited it with improving their academic achievement, a small minority called such use outright misconduct, and nearly everyone described an uneven playing field in which AI-assisted work earned better grades than honest effort while independent workers lost their sense of diligence. The sharpest feature of the account is the students' definition of plagiarism, which is technically defensible and incomplete — if plagiarism means reproducing someone else's words, a machine-written text that copies nothing is not plagiarism — which is why the authors argue the definition must expand beyond copying and pasting, following Ka and Chan's (2025) "AI-plagiarism", and why they place students' own beliefs, not only institutional rules, at the center of ethical use.

Sharma (2026) takes the pedagogical inversion a step further by extending Eaton's postplagiarism frame from an ethical orientation into assessment design. Integrity, on this account, is enacted through evaluative judgment — the learner's capacity to weigh options, justify academic choices, and assume responsibility under epistemic uncertainty — and made visible through four practices: annotated decision trails, verification and accountability practices, oral defense and dialogic accountability, and draft differences with version history. Detection is retained only as a supplementary layer for clear misrepresentation or deliberate outsourcing of intellectual labor, never as the primary infrastructure of integrity, because it asks whether GenAI was used rather than how the decisions behind the work were made. The argument also names the equity risk that detection-centered models fall hardest on learners who rely on generative tools for linguistic or cognitive Scaffolding.

A third route sits between detection and redesign. Akçapınar (2026) predicts AI-assisted cheating risk from early-semester LMS traces with an AUC of 0.763, and frames the output as low-stakes academic guidance — reminders, assignment follow-up, brief check-ins — rather than evidence of misconduct, insisting the score stay separate from grading and disciplinary records.

Connections

Academic integrity connects to Assessment Validity, AI Literacy, AI Detection, Authentic Assessment, Assessment, Educational AI Policy, AI Regulation in Education, Ethics, and Equity. It is the ethical dimension of AI in education, inseparable from Over-Reliance and the broader question of how Generative AI reshapes Higher Education and K-12 learning.

- **Systematic-review synthesis.** A PRISMA review of 25 studies (Balalle & Pannilage 2025) finds AI acts as both a threat (AI-generated writing, paraphrasing tools) and a detection tool (Turnitin AI scores), that detection software is unreliable for AI-generated work, and that institutions must build a culture of academic integrity through clear policy, assessment redesign, and ethics training rather than policing alone.(Reassessing academic integrity in the age of AI: A systematic literature review on AI and academic integrity)

Integrity is a central concern but a rare outcome. Across 394 GenAI higher-education studies, academic integrity and ethics were among the outcomes targeted least often (Lin et al. (2026)). - **From policing to dialog: learning verification.** A practitioner account of Grand Canyon University's institution-wide framework (Mandernach 2026) argues detection is unreliable and formal integrity processes rarely reach resolution, leaving faculty with "suspicion without recourse." GCU instead adopted **learning verification** — asking students to demonstrate understanding of their submitted work in a brief conversation — reframing integrity from a compliance problem to an assessment problem. It restores faculty authority, shifts students from "how not to get caught" to genuine engagement, and treats AI use as acceptable when the student can demonstrate learning; students' initial anxiety about verification underscores that surveillance-heavy policy can corrode Trust.

- **GenAI defeats autogradable homework (2026):** ChatGPT passed every one of 150 test sessions on deliberately hardened, autogradable Qiskit (quantum computing) homework designs — personalization, hidden references, reflections, simulator execution — showing that rubric-based graders cannot reliably distinguish AI-completed from student-completed work and arguing for direct assessment of understanding (ChatGPT Solves All Tested Qiskit Homework Assignments).
- **Evaluation in the age of AI — output as evidence (2026):** a university-level analysis argues the AI assessment crisis is a misalignment between assessment design and learning outcomes, not just dishonesty; it documents surveillance harms (lockdown browsers, eye-tracking), a "Disclosure Trap" (students fear declaring AI use lowers marks), a performance gap that grades socioeconomic status (paid vs. free Large Language Models (LLMs) tiers), and "pedagogical burnout" among faculty policing AI — recommending process-based evaluation over detection (Evaluation in the Age of AI: Output as Evidence of Learning).

Newer evidence: ethical reasoning, detection limits, AI marketing, and ghost students

A wave of recent research sharpens the picture of academic integrity in the age of generative AI:

- **Secondary students reason about AI-giarism situationally, not as a fixed rule.** Chan (2026) shows that secondary students' ethical reasoning about "AI-giarism" is nuanced and context-dependent — many see AI-assisted work as acceptable when it supports understanding but

problematic when it substitutes for their own effort — challenging the assumption that students simply lack integrity or that a single policy can capture their ethics.

- **Students' own concern is learning loss, which the misconduct frame misses.** Ting et al. (2026) interviewed 14 undergraduates and found them drawing a line not at AI use but at AI producing work they had not done, and asking where the tool was helping and where it was doing something they needed to learn to do themselves. The authors argue that the student–faculty conversation is framed too narrowly around misconduct, since students in their accounts worry about losing skills and about whether the work is still theirs — concerns close to those of their instructors. Their reasons for holding the line were also heterogeneous (skill loss, ownership and pride, moral objection), and pressure from deadlines, workload and grades overrode them in individual cases.
- **Authentic assessments alone cannot safeguard integrity.** Kofinas et al. (2025) find that markers generally **cannot distinguish** assessments with GenAI input from those without, and that the level of assessment authenticity has **no impact** on the ability to safeguard against or detect GenAI use. The higher-education sector "cannot rely on authentic assessments alone to control the impact of GenAI" — a direct challenge to the assessment-redesign strategy, which must be paired with other measures.
- **Integrity guidance must extend into the research process, not just teaching.** Dai & Chan (2026) find postgraduate researchers enact AI Literacy across research tasks and argue that responsible-use policies, which currently focus on teaching and assessment, must scaffold the ethical dimensions of GenAI use in research — where concerns center on originality, authorship, data privacy, and skill degradation rather than plagiarism alone.
- **Purpose must precede policy.** Taylor & LaCroix (2026) argue that whether GenAI use constitutes misconduct depends on the university's *purpose*. Rising misconduct cases reflect structural incoherence in the neo-liberal university, where technological enthusiasm, corporate influence, and policy enforcement conflict — leaving students accountable for behaviors implicitly shaped by the institution. Universities cannot credibly enforce integrity without coherence between stated mission, pedagogy, and technology practice.
- **Psychological and behavioral determinants.** Frontiers research maps the psychological mechanisms and behavioral determinants of academic integrity under AI — how attitudes, self-efficacy, norms, and perceived consequences shape honest use — connecting integrity to Motivation, Self-Efficacy, and AI Literacy as behavioral constructs rather than pure rule-following. Tabares-Cruz et al. (2026) quantify these in a SEM of 980 Ecuadorian university students, ordering academic-integrity and transparency dispositions first, followed by AI literacy, critical verification, institutional guidance, self-regulation, and data protection — with integrity dispositions and AI Literacy together explaining a substantial share of ethical GenAI use and outpacing institutional rules alone.
- **AI marketing normalizes use and framess "cheating vs. competing."** Sobo et al. (2025) show AI is marketed to students as a practical necessity ("Make your writing sound more natural to avoid being mistakenly flagged"), and students feel compelled to adopt it to stay competitive even while worrying about dependency and learning forfeiture — an internalized entrepreneurial imperative. This points to the need for marketing literacy as part of AI integrity education.

- **AI humanizers expose the performative cycle of detection — and the market built into it.** Roe et al. (2026) catalogue 55 AI-humanizer websites that alter AI-generated text to evade detection, framed through Goffman's dramaturgy, with a Multimodal AI critical discourse analysis of the three highest-scoring. Humanizers make misconduct discursively absent and perform legitimacy instead of assuming it: unexplained university and corporate logos placed under the text box, unverifiable user claims (about 3 million, 10,000 students and 1.5 million across the three sites), 99.8%–100% success rates, and mystification through "1.6 trillion parameters" — while no site listed a registered business address. The paper's contribution to integrity policy is that this is not a side market but the mirror image of detection: one vendor sells a classification of authorship, the other sells the promise of changing it. Students appear simultaneously as users of AI production tools, subjects of detection, customers for evasion services and sources of behavioral data, and each layer of the loop has a commercial interest in not interrupting it — so the arms race is structurally unending, reinforcing the shift from policing to assessment design and AI Literacy.
- **Enforcement, not detection, is where the conversation lives.** Across 270,929 AI-related records from 26 education subreddits spanning three and a half years, the academic-integrity cluster held 37.1% of the discussion and Misconduct Enforcement was the single largest theme at 12.1%, while 32.3% of faculty–student threads sat inside detection and enforcement disputes (Yüce et al. (2026)).
- **Ghost students and the agentic-AI verification gap.** Bozkurt, Crompton & Fell Kurban (2026) introduce the **"ghost student"**: a digital surrogate created by coupling LLMs (the "mind") with agentic AI browsers (the "body") that can navigate LMS, engage content, and complete assessments with human-like mimicry, making the actual learner's presence optional. This creates a **verification gap** that traditional proctoring and detection are structurally unable to close — an integrity threat that grows as AI becomes agentic rather than merely generative.

The clearest disciplinary case for redesign over detection comes from computing education. A systematic review of 72 studies of generative AI in computing and programming education (Kumar, Wongsirichot and Nanthaamornphong 2026) found only **three** studies examining AI-detection mechanisms — the thinnest evidence base of the 14 themes it consolidated — while course and assessment redesign was supported by 25. The review treats the imbalance as diagnostic rather than incidental: institutions have largely updated policy documents without redesigning assessments, and most instructors sit at a *tolerance* rather than *transformation* level of integration, with 70% of one national faculty sample explicitly requesting training on AI-resistant assessment design. Its recommended response is concrete: add an oral component or other process-visible element to at least one high-stakes assessment per course, and make critical engagement with AI output (reading, testing, modifying, explaining, critiquing) a graded, observable component of student work rather than an aspiration left to student discretion (Assessment Validity). A PRISMA review of 72 higher-education assessment studies finds three design responses recurring in response to GenAI — process orientation, authenticity, and oral and dialogical approaches — framed as layering onto existing validity, authenticity and alignment principles rather than displacing them (Crompton and Burke (2026)). - **Fabricated references have reached the published computing-education record.** Denny et al. (2026) traced 113,588 references from 5,225 computing education papers in the ACM Digital Library against the full corpus of 723,930 publications and 15,872,533 references, manually verified 828 suspicious records, and

confirmed 30 references containing verifiably fabricated bibliographic information across 14 papers, all published in 2025 or 2026. At the SIGCSE Technical Symposium the verified count rose from 3 in 2025 to 17 in 2026, sitting in 2.3% of 2026 proceedings papers, and hallucinated references appeared across five SIGCSE-sponsored or in-cooperation venues in 2025. The number is intact only with its counterweight: most flagged references were benign — 229 were ACM metadata mismatches where the PDF was correct and 188 were valid bibliographic variants — so the venue figure is a deliberate lower bound. It lands on authors, not only on Peer Assessment, because reviewers checking reference lists cannot verify every entry, and Large Language Models (LLMs)-assisted drafting makes an invented but plausible citation cheap to produce.

- **Clarity without redesign moves misuse sideways rather than removing it.** Petricini & Zipf (2026) plot AI use on two axes — students' intention and effort against the clarity and support the environment provides — and report that the most populated quadrant in their interview data was *anxious compliance*, where students hide legitimate help (grammar support, concept explanations, organizing their own ideas) to avoid false accusation. Their warning is directional: where rules become clear but Assessment still rewards speed and product, policy-aware students shift into *efficient circumvention* rather than into *virtuous tool use*. Austin (2026) reaches the same place from the assignment side — when agents satisfy every rubric criterion without visible reasoning, grading the decision trail (confidence calibration, rejected AI suggestions, course-specific constraints) replaces detection, which she notes misfires in both directions.
- **Employers discount grades they believe AI produced — and converge on in-person verification.** In a survey experiment with ~1,750 U.S. hiring professionals, Boyd-Swan & Reynolds (2026) show that framing student AI use as an assistive tool left applicants unpenalized, while framing it as a *substitute for student effort and ability* decreased interview likelihood and — more starkly — salary-negotiation willingness, concentrated among high-GPA applicants regardless of race/sex. Asked what would ease concerns, both framing groups selected only one remedy in common: in-person tests. The experiment isolates belief (not actual AI use), so it shows how the *signaling* channel alone moves hiring outcomes — early evidence that labor markets may push assessment back toward presence-verifiable formats, the same design direction the ghost-student literature urges institutions to adopt.

The first Theory of Planned Behavior study of GAIT-based misconduct intention extends this picture: among 186 undergraduates, Baig and Paparo (2026) found attitudes toward misconduct, subjective norms about it, and positive attitudes toward AI each predicted intention, while negative attitudes toward AI did not, and higher perceived likelihood of detection predicted lower intention — a deterrent undermined by the documented unreliability of AI detection tools.

Integrity policies are shifting from who wrote the words to who had the ideas, and the detectors are being rebuilt to match. IdeaLens predicts idea provenance from an outline rather than from prose: on 50 stories that people wrote from scratch following AI-generated plans it flagged 68% as AI, against 8% for Pangram 4 and 0% for its prose-trained control, and it labeled 94.7% of AI-polished human text human (Rajendhran et al. (2026)). Its own ethics statement calls the output a statistical estimate that must not be used by itself as conclusive evidence of AI use.

Gillette et al. (2026) document the regime from inside one faculty: teachers who had changed assessment formats said it was "virtually impossible to say whether a student has used AI in the writing of assignments",

while angry students asked for appeals to conscience and “shaming” rather than detection. - **Better sensing does not change what the assessment can certify.** A YOLOv11 pose-estimation proctoring system reporting 99.56% classification accuracy illustrates the limit of the detection route: it measures posture against a behavioral label, reports no ground truth on misconduct, and offers no subgroup analysis (Arif et al., 2026). The remedy Villanueva argues for is sufficient evidence of learning at key stages, not maximum surveillance of every submission.

Integrity language in international policy does not fix an operational meaning, and that is the finding rather than the gap. Hashem (2026) analyzed four UNESCO and OECD publications from 2023 to 2026 through critical discourse analysis and found eight recurring terms — responsibility, transparency, trust, human agency, originality, authenticity, responsible use and augmentation — carrying normative weight while shifting referent between documents. UNESCO holds providers responsible for core values and educators responsible for pedagogically appropriate interaction; the OECD relocates the same term into teachers’ professional judgment.

The OECD (2023) records that as of early 2024 none of eighteen surveyed countries had specific generative AI regulation for education and nine had delegated governance to the school level. Read through Ahmed’s non-performativity, the vocabulary expresses ethical responsiveness without any mechanism to enact it, so responsibility is invoked by every actor at once and located in none. Hashem names the result a changing **cheating habitus**: dispositions toward legitimate participation recalibrated under chronic indeterminacy, stratified by the academic capital students bring, with cheating and being cheated treated as concurrent conditions rather than alternatives. All of it is proposed from policy text, not observed in students.

Common Misconceptions

- **“Detection tools identify AI writing.”** AI-generated text has **passed as human-authored in up to 80% of cases**, while the evidence for detection puts **machine detection at about 80% against 78.4% for human raters**. Human and machine judgment are almost equally (un)reliable, so a detection verdict is not evidence of authorship.
- **“The problem is marginal.”** The volume is far from it: a **six-year analysis of a large-enrollment CS2 course** found **45.7% of Spring 2026 students flagged**. Nearly half a cohort, which makes this a mainstream design problem rather than an edge case.
- **“Instructors know which assessments are vulnerable.”** In a biology department, instructors **perceived only in-person proctored exams as minimally vulnerable**, while outside-of-class assignments were seen as exposed. The perception matched the obvious case and treated everything else as safe.

Teaching

> **Teaching** — how AI reshapes the work, identity, and agency of educators. With 50+ articles examining this dimension, the knowledge base documents a fundamental transformation: from sole knowledge authority to orchestrator of human-AI learning environments. This page goes beyond describing that shift — it details what teachers actually *do* differently, how they can adapt their practice, and how they connect to Learning Design, AI Literacy, and Academic Integrity.

> Malyn-Smith et al. (2026) call this the more-human paradox: in six 2030 scenarios co-constructed by 20 researchers from 13 countries, AI saturation intensifies rather than displaces human pedagogical work. The scenarios describe AI as "the air-handling system of the learning ecosystem" — you notice it only when it malfunctions.

Questions to Consider

- The page describes the teacher's shift 'from sole knowledge authority to orchestrator of human-AI learning environments.' What do you gain and what do you lose as an educator when you stop being the main source of content?
- It argues AI reallocates a teacher's scarcest resource — attention — from producing materials to interpreting learners. Does that reframing ring true, and what would you actually do with the reclaimed time?
- Research cited on the page shows teachers as active AI designers — writing the prompts and scaffolds that shape how AI behaves for their students — rather than passive consumers. What would it take for you (or teachers you know) to feel like a designer of AI rather than a user of it?
- At the far end of the 'teacher-AI teaming' spectrum, the teacher orchestrates a team of human learners, AI tutors, and curriculum resources. Where does human judgment remain irreplaceable in that team, and what might quietly erode if the orchestration is left mostly to AI?
- If the teacher's attention is reallocated from producing materials to interpreting learners, what new competencies and risks does that introduce — and who supports the teacher in developing them?

Introduction

Teaching here names the professional role as AI reshapes it: less content delivery, more orchestration of human and machine participants, interpretation of what learners actually understand, and design of the conditions under which AI use is legitimate. The pages collected under this concept document teacher–AI teaming and workflow change, the competencies the role now demands, and the tension between efficiency gains and the attention that individual support requires. It sits alongside Educational Development, AI Literacy and Assessment as one of the roles that determines whether AI integration changes practice or merely decorates it. The learning sciences are the research field whose evidence reshapes this position: they

describe and test how learning happens and which designs change it, while this page covers the classroom role that has to act on that evidence in the moment.

How AI transforms teaching

- **From instructor to orchestrator:** Five levels of teacher-AI teaming and agency orchestration research map the spectrum from AI as tool to AI as teaching partner. At the far end, the teacher orchestrates a team that includes human learners, AI tutors, and curriculum resources rather than delivering all content themselves.
- **Workflow transformation:** How AI Is Changing Teaching Workflows. documents how AI shifts teacher time from content delivery to higher-value activities like individual support, Feedback, and Curriculum Design. The teacher's scarcest resource — attention — is reallocated from producing materials to interpreting learners. A systematic review of language educators (Li et al. 2026) corroborates this: educators value GenAI most for preparatory work (lesson planning, materials creation, writing support) while hesitating on live classroom use, and their adoption is shaped by professional-identity, pedagogical, technical, institutional, and academic-integrity factors — with competency gaps mapping to episteme (understanding AI's capabilities/limits), techne (Prompt Engineering, AI-enhanced task/assessment design, detecting AI-generated text), and phronesis (ethical judgment, bias/privacy handling, context-sensitive judgment). documents how AI shifts teacher time from content delivery to higher-value activities like individual support, Feedback, and Curriculum Design. The teacher's scarcest resource — attention — is reallocated from producing materials to interpreting learners.
- **Competency demands:** Teacher AI competency frameworks define what educators need to know, from basic tool fluency to pedagogically grounded orchestration. Adoption studies identify the real barriers: confidence, institutional support, and workload concerns. Bai & Hsieh (2026) add an empirical weight to this in an SEM of 898 Chinese university teachers: GenAI-supported teaching innovation depends less on isolated AI technological knowledge and more on pedagogically and disciplinarily embedded AI competence (AI Literacy and professional identity), both of which partially mediated the competence → innovation relationship — a signal to build faculty development around embedded, identity-linked AI competence rather than tool-only training.
- **Readiness as a design capability, not an attitude:** Charles (2026) argues that teacher readiness for AI-rich interactive learning cannot be read off adoption, confidence, or digital competence, because none of these predicts the quality of the designs teachers actually produce. Readiness-by-design is enactment-oriented: teachers mobilize AI-related pedagogical knowledge, pedagogical beliefs, Self-Efficacy, and ethical orientation through *design mediation* (tool selection, task and prompt design, scaffolding, transparency, verification, assessment redesign, accessibility planning, and human oversight) inside an institutional and policy ecology that enables and moderates the translation. Two claims carry practical weight. Self-efficacy is a mobilization resource rather than a quality indicator, so confidence without AI-related pedagogical knowledge or ethical orientation can accelerate poor design. And policy clarity and material support are separate moderators, so a well-resourced school can still leave teachers guessing what is permitted. Charles also declines to

equate non-use with unreadiness: a reasoned decision to withhold AI can itself demonstrate readiness.

- **Co-design and agency:** Teacher-authored prompts and vibe coding for teachers show educators as active AI designers, not passive consumers — writing the prompts and scaffolds that shape how AI behaves for their students. In children's STEAM arts lesson planning, Luo and Tahir (2025) experimentally confirmed that *how* the teacher delegates to ChatGPT matters: filling content gaps in a self-outlined lesson (the method favored by 60% and recommended) preserved teacher design autonomy while still raising expert-rated plan quality (median 20.5 vs. 17.6, p = .002, large effect), outperforming having AI generate whole plans or merely checking a finished one. AI served chiefly as an inspiration and gap-finding collaborator rather than a source of fully original innovation — reinforcing that the teacher remains the design agent and judge of output, including catching child-safety and cultural-bias flaws the tool missed. A systematic review of teacher–AI co-design of learning tasks (Wang, Liu & Islam 2026) finds this co-designer stance remains uneven — the dominant mode is still AI as assistant/content generator — and Talebzadeh (2026) shows the teacher's agency as "bilingual learning designer" is what turns AI-designed group activities into differentiated, ZPD-aligned instruction.
- **Authoring a bot is not the same as controlling what it teaches.** Twenty-seven middle school teachers who configured a purpose-and-rules chatbot authoring tool saw only partial fidelity in the generated behavior - alignment fell from 88.9% for responsiveness and 81.5% for persona to 70.4% for rules and 59.3% for purpose, and rule adherence varied by the model chosen. That is the execution/evaluation gap that makes the teacher-as-designer role a rehearsal of intent rather than a guarantee of it (Riahi et al. (2026)).
- **Preservice preparation:** TPACK-based training and Educational Development programs prepare future teachers for AI-augmented classrooms before they enter them. Simulated-student role-play extends this into hands-on practice: a custom ChatGPT bot (Student GPT) playing a mathematically misconception-ridden middle schooler lets preservice teachers rehearse diagnosing and guiding student reasoning in a low-risk setting, preparing them for a central teaching task — reading and remediating student thinking.
- **A teacher-facing frontier the evidence base has barely entered:** Štefánik et al. (2026) assemble **Edustories**, 1,492 teacher-written case studies of real elementary and high-school classrooms — challenging student behavior, the intervention the teacher attempted, and what followed — precisely because most AI-in-education research has targeted individualized student assistance while most teaching happens in collective classrooms. Benchmarking four language-model families on predicting whether an intervention succeeded, the strongest models reached 58% accuracy against 64% for human experts; the authors read the gap in both directions, as a limit on current teacher-facing assistance and as evidence of emerging potential. What the page gains from it is a measured ceiling rather than a capability claim: advice to teachers needs to be better than expert judgment before it can be trusted, and today the ordering is the other way. A parallel gap appears in Yalçın et al.'s (2026) PRISMA review of 46 empirical studies of GenAI in higher-education programming: instructor roles and institutional practices were among the least studied areas of the field, and 26 of the 46 studies gave no codable description of their instructional

approach, so the design decisions that produced reported outcomes are often invisible even to other instructors.

- **Where AI actually enters the work, by task:** Holster (2026) separates adoption from allocation using TALIS 2024 data from 56,669 teachers, with an allocation sample of 24,058 AI users across 46 education systems. A task rated one point above a teacher's own mean demand was more likely to receive AI help (OR = 1.163), but the direction differs by task. Planning rises with demand (OR = 1.084), assessment and marking falls (OR = 0.921), and Special Education support and adaptation rises steeply (OR = 1.442, a predicted spread from 34.0% to 50.3% across the demand range). The competency and policy reading is that teachers already keep high-stakes marking human while reaching for AI on individualized adaptation work, so guidance that treats teacher AI use as a single behavior will miss where support is actually needed.

What the changing role actually looks like: concrete examples

The abstraction "orchestrator" is easier to grasp through concrete, day-to-day shifts in instructor work:

- **From writing every handout to curating AI-generated drafts.** An instructor who once spent an evening building a differentiated worksheet now prompts an AI to produce three versions at different difficulty levels, then spends the same evening *reviewing and adapting* them — a shift from authoring to editorial judgment. Curriculum-as-Code workflows make this pipeline explicit, and Kibar & Ilgaz's systematic review shows AI acting as a "co-worker" that drafts content the designer then refines. Expert validation of AI-generated science lesson plans makes explicit what that editorial judgment must weigh: Karaismailoglu, Surmeli and Yildirim (2026) found eleven Science Education specialists rated ChatGPT-4 and an education-focused tool's sixth-grade plans as usable drafts — 7 of 11 judging them "applicable by correction," only 3 directly "Applicable" — and preferences diverged from raw scores (7 preferred the higher-scoring education-focused tool, 4 the general-purpose plan) because judgment weighed affective and contextual dimensions beyond structural fidelity. Teachers remain the arbiters of whether and how an AI draft becomes a teachable, contextually grounded lesson.
- **From lecturing to real-time coaching.** Rather than delivering the same explanation to the whole class, teachers increasingly route routine questions to an AI tutor and focus face-to-face time on the students who need human judgment — workflow studies document exactly this reallocation of attention.
- **From grading to designing assessments that AI can't game.** Instructors stop relying on recall-based tasks that LLMs trivially solve and instead design authentic assessments, assessment scales, and formative tasks that preserve Learning Gains.
- **From teaching content to teaching *use*.** The teacher's job increasingly includes modeling how to prompt, evaluate, and responsibly use AI — an AI Literacy curriculum woven into every course, not a separate subject.
- **From reading dashboards to acting on them — contextually.** Mejia-Domenzain et al. (2026) show that how teachers actually use analytics dashboards diverges by context: flipped-classroom (university) teachers followed a sequential exploration and favored course-level adaptation and showing dashboards in class, whereas vocational teachers revisited summary pages and used the

tool mainly for individual coaching sessions. The actions teachers proposed were shaped by the content represented and their teaching level rather than the plot type — university teachers favored weekly tests and course adaptation, vocational teachers direct, individualized coaching. This points to context-aware dashboard design and differentiated teacher support needs rather than a one-size-fits-all analytics interface.

- **From receiving alerts to judging them.** Swidan (2026) followed one teacher and eight high-achieving high school students in a GeoGebra geometry lesson where Dash4Emotion framed students with red rectangles signaling negative emotion, and found that the alerts did not drive outcomes — the teacher's move after each alert did: reframing Mira's task from finding a minimum value to the geometric locus of minimal points reopened her exploration, three simultaneous alerts prompted a whole-class reframing, and one period's deliberate non-intervention was itself a pedagogical decision. The study's stance is that an AI-generated emotional alert is a cue to be interpreted alongside what the teacher can see, not an instruction to be obeyed.
- **From gatekeeper to principled facilitator of collaboration feedback.** The Community Builder (CoBi) classroom pilots show the teacher role decisively shapes *implementation integrity*: teachers who used the AI's noticings and visualizations to spark Metacognition and critical reflection about collaboration achieved high-integrity use, while those who let the system drift into performance-monitoring — or veer off into general AI discussions — did not. Teachers also worried about being put "on the spot" by real-time feedback and preferred pre/post-action review over live display, underscoring that orchestrating classroom-wide collaboration AI demands substantial professional learning, not just tool fluency.
- **From instructing with AI to standing in for it.** Where the Digital Divide leaves no device for each student, the teacher can become the *physical interface* to the system — a proxy rather than an orchestrator of it. In Rodrigues et al.'s (2026) "AIED unplugged" model, students keep working with paper and pen while the teacher photographs their solutions, and the AI returns personalized exercise lists and error-specific Feedback to be handed back. This is a clustered quasi-experiment across 19 authentic Brazilian elementary classes rather than a prototype demonstration, and its two results bear on the role directly. First, the learning advantage over usual practice came from a single 50-minute *teacher-training* session, not the technology: the training and training-plus-system conditions did not differ on gains (−4.33, 95% CI [−17.29, 7.23]), so preparation, not the tool, is the active ingredient. Second, the system's own benefit ran *indirectly, through the teacher* — reduced Effort mediated a positive effect on gains (3.649, 95% CI [1.097, 6.398]) — so the effect reaches students the AI never touches, and the capture-and-verify labor the teachers described (photographing sheets, waiting for processing, correcting recognition errors) is part of the pedagogical cost of extending AI to under-resourced classrooms.
- **From information provider to learning designer.** Hochberg and Waitzman (2026) followed 93 teachers through an eight-week AI program and found practice shifting toward heutagogical design for learner agency, though the self-reported shifts were not significant after adjustment and learner outcomes were not measured.

The orchestration metaphor

The dominant metaphor in the knowledge base is *orchestration*: teachers coordinate human learners, AI tutors, and curriculum resources. This contrasts with replacement narratives — AI augments rather than substitutes for human teaching. Empirical evidence supports this stance: a PRISMA-guided systematic review of 42 studies (2023–2025) found LLMs match human raters on short, well-structured tasks but that performance declines on longer, multilingual, and nuanced work — concluding LLMs cannot fully replace teachers and that hybrid, human-in-the-loop assessment systems achieve the highest grading effectiveness (Can ChatGPT Replace the Teacher in Assessment? A Review of Research on the Use of Large Language Models in Grading and Providing Feedback). The orchestration lens reframes the instructor's core skill as *judgment*: deciding when a human, an AI, or a designed learning activity is the right instrument for a given learner and moment. A 2026 PRISMA review of 29 studies of Teacher intervention in K-12 AI-based instruction: a systematic review of processes, strategies, and effects sharpens the metaphor into a four-phase cycle — monitoring, judgment, intervention, orchestration — and shows why no phase can be assumed. Teachers preferred shared control, accepting, modifying, rejecting or overriding AI suggestions; some deferred intervention deliberately so students could struggle productively first; and dashboards that expanded awareness could also overload attention or exceed what one teacher could physically act on. Its three strategies — pedagogical translation of AI output, design of learning support, and reconstruction of interaction structures — describe the work as recontextualization rather than approval, which places the teacher closer to mediator than to the human-in-the-loop reviewer role. Classroom observation names the same behaviors as types. Six lessons with an experienced teacher added three orchestration types to Drijvers' four — dashboard-monitoring, AI-correcting and AI-mediating — with the teacher's content and ethical roles most visible when he corrected AI-generated feedback (Noh & Kim, 2026).

Evolving and critical teacher roles

Recent work expands the orchestration metaphor into richer role conceptualizations:

- **Co-orchestrator across activity transitions.** Yang et al. (2026) use participatory speed dating with 17 teachers and 13 students to map how control should be distributed across the stages of a classroom activity — the before, during, and after transitions between individual and collaborative work — in a co-orchestration tool supporting real-time dynamic pairing. The design principle that emerges is that control is *not* a fixed point: teachers and students want different amounts of agency at each stage, and the tool should let the teacher adjust grouping, activity transitions, and intervention timing in real time while retaining a teacher override. This positions the teacher as a **co-orchestrator of the whole live learning environment** — a role more specific than the general orchestration metaphor, focused on the granular, moment-to-moment decisions of who works with whom, when, and with what support — and it connects individual-tutoring research to classroom-level design.
- **The "cognitive choreographer."** Posthumanist frameworks recast the teacher as a *cognitive choreographer* who orchestrates cognition distributed across biological and artificial systems, moving beyond instrumentalist models like Technological Pedagogical Content Knowledge (TPACK) and SAM.(Pedagogical Symbiosis: conceptualizing the Post-Human Learner in the age of cognitive AI)

- **Facilitator, co-investigator, ethical supervisor.** In science learning, teachers' roles shift from knowledge transmitters to facilitators and co-investigators, and gain new responsibilities as ethical supervisors of students' responsible AI use.(Artificial Intelligence in Science Learning within the Framework of Situated Learning Theory: A Qualitative Investigation of Teachers' Perspectives)
- **Mediator of learning principles.** Educators operationalize age-old learning principles (experiential, situated, and distributed cognition) through AI, treating AI as a tool that enhances rather than replaces the educator's guiding role.(Empowering Educators: Operationalizing Age-Old Learning Principles Using AI)
- **Critical mediator who turns AI output into an object of critique.** Canonigo (2026) followed ten secondary mathematics teachers through an eight-week ChatGPT-4 intervention and identified five mediation practices: AI-generated problem posing, hint scaffolds designed to fade, critical comparison of AI output against students' own work, differentiated prompting (a visual analogy for a struggling student, a cubic extension for a peer), and AI as a reflective dialogue partner. Where teachers enacted these, output became something to argue with rather than an answer key, and students moved toward conjecture and metacognitive questioning; where mediation was absent, authority migrated toward the algorithm, with students consulting the AI before their teacher and returning only for validation, prompting one teacher to describe the move from "oracle" to "editor." The study's equity finding is the sharp one: across 300 model responses, the free-tier model was inaccurate in 32.7% of instances against 12% for the premium model ($\chi^2(1) = 17.5$, $p < .001$), so teachers in the under-resourced school called it "borderline useless for mathematics." Tool quality, not just tool access, becomes a pedagogical variable, and one teacher's school acceptable-use policy was a decade old and silent on AI, leaving the governance gap to the classroom.
- **Unsettled and vulnerable professional identity.** Farazouli et al. (2026) document the *emotional* side of role reconfiguration: 24 Swedish university teachers experienced GAI's emergence as alarming and overwhelming, reporting a "state of vulnerability" (low confidence, insecurity, fear of "not being ahead of students") and feeling "stuck" between utopian and dystopian discourses. GAI prompted them to re-evaluate their priorities — cultivating Critical Thinking, Evaluative Judgment, and ethical GAI use — and to question their own and the university's future role in a landscape that felt "out of control." This frames the teacher-role shift as identity-level and emotionally charged, not merely a skills or workflow change.
- **Academic developers as digital mediators, including as a brake.** Sithole (2026) interviews twelve academic developers and learning designers at two South African Historically Disadvantaged Institutions and finds the role shifting from facilitating reflective teaching toward technological intermediary and problem-solver, with mediation spanning pedagogy, ethics and institutional politics. The distinctive move is treating slowing down as part of the job: one participant describes translating between "what management wants, what the technology can do, and what lecturers are actually worried about," and naming plagiarism, student dependency and the outsourcing of thinking before enthusiasm sets the pace — "It is not just technical support; it is also negotiation." The same study documents the affective cost ("I feel like an impostor. I am learning AI as I go, but the institution expects expertise") and the professional-learning response: peer spaces that test and deliberately break tools, aiming at judgment rather than skill, and an explicit refusal of the adoption-or-resistance binary — "I am not anti-AI; I am pro-context."

- **Principled selectivity instead of adoption or resistance.** Adiozaman and Segar (2026) interviewed two academics with more than ten years' experience three times across a single semester and found identity work organized around three interrelated tensions — pedagogy versus platform, educator versus facilitator, and care versus compliance — which resolved not into a settled position but into *principled selectivity*: context-sensitive decisions guided by pedagogical values, ethical commitment and professional judgment. They describe a trajectory from implicit orientation, through mid-semester strategies such as asking students to explain their thinking and redesigning tasks and assessment, to stances that stayed deliberately open rather than fixed, with refusal of a particular use treated as a legitimate exercise of judgment rather than a failure to adopt. This supplies the constructive counterpart to the vulnerability documented above: what the role shift demands is judgment, so institutional responses built around tool training address the wrong problem.
- **Semi-autonomy as the preferred operating point.** Dai et al. (2026) surveyed 287 GenAI-experienced teachers in 27 countries and regions and found them placing the tool at the *semi-autonomous* levels of an automation scale — 130 chose Level 2 ("teacher assistance"), 94 Level 3 ("partial automation"), and exactly one chose Level 6 — describing it as "auxiliary", "scaffold", "complement" or "partner". Perceived usefulness dominated their adoption intention ($\beta = .832$, $p < .001$), while perceived artificial autonomy influenced intention only indirectly through usefulness, and risk aversion depressed intention without denting usefulness because their worries attached to *students'* use — cheating and integrity, weakened foundational knowledge and higher-order thinking, hallucinations, reduced human interaction, and ethical, legal and Equity risks. The authors' "frenemy" label captures the stance precisely: GenAI valued as a support tool but distrusted as an autonomous agent. The corollary for the teaching role is that teachers want to remain the deciding agent and to settle use case by case — discipline, student needs, task type, timing — so orchestration tools should be built around human oversight and case-level judgment rather than autonomy promises.
- **Authority stays with the teacher; capability expands only inside it.** Reichert, Briceno, Tabarsi & Barnes (2026) gave six secondary teachers across grades 6-12 (social studies, mathematics, animal science, science, and computer science and robotics) the task of paper-prototyping an LLM chatbot for their own classroom, and found that every prototype encoded the same stance: the system was a *bounded expert*, specialized but confined to a defined domain and supervised by the teacher. Teachers drew two boundaries. *Authority* boundaries followed from professional and legal responsibility — control over what students learn and how they are kept safe could not be delegated, so oversight (complete conversation logs, real-time alerts for inappropriate queries, and manual override) was treated as a duty of the role rather than a check on the tool. *Expertise* boundaries followed from what the model cannot know: individual students' histories, classroom dynamics, and institutional norms. Delegation was then allocated selectively across instruction — teachers welcomed AI to present content, supply practice problems, scaffold, and give formative Feedback, but kept informing students of objectives and summative Assessment themselves. This supplies the semi-autonomy preference documented above with a concrete architecture: the teacher's authority is the fixed element and AI capability grows only within it.
- **Teachers as value-laden graders.** Luo & Dawson (2026) show that grading GenAI-assisted work is not a neutral, criteria-based act but a value judgment shaped by teachers' conjecture about who

the student is (honesty, diligence), what they are capable of (independence, GenAI skill, disciplinary mastery), how they relate to others (trust), and whether the decision leads to good outcomes (fairness, beneficence). Teachers often lack awareness of the value orientations underlying their grading, and these vary by discipline (humanities more critical of GenAI use; hard/applied sciences fewer grading challenges) and epistemological stance (absolutist/multiplist/evaluativist). This positions the teacher as an evaluative professional whose judgment — not just tool use — must be supported and made transparent.

- **Teacher as the arbiter of pedagogically meaningful explanations.** Because teachers' trust in AI recommendations rises when explanations are framed in *their* curricular/pedagogical language rather than in raw model internals, effective tools must "speak" the teacher's domain. In a within-subject experiment, Feldman-Maggor et al. (2025) found domain-driven explanations of an AI grouping tool were trusted and accepted far more than data-driven feature-importance ones, positioning the teacher's pedagogical vocabulary as the interface through which AI earns trust and use — and their judgment of whether an explanation is pedagogically sound as a deciding factor in adoption.
- **Facilitator whose function can be partly delegated.** Kuhail et al. (2026) had 32 STEM students debate under a human moderator, an AI chatbot (GPT-4, prompted with the behaviors expected of faculty: neutrality, equal speaking time, short directions, on-topic enforcement, follow-up questions, de-escalation), or each in turn. They found no significant difference on effectiveness, enjoyment, satisfaction, utility, or intention to reuse ($t = 0.23$ to 1.30, $p = 0.198$ to 0.818). The authors read the null result as normalization of human-AI collaboration in rule-bound discussion, not as equivalence. The route to reuse did differ: under human moderation satisfaction drove intention to use, whereas under AI moderation perceived utility did (0.806 against 0.495), so an AI-facilitated activity survives on demonstrated usefulness rather than on how enjoyable it feels. The practical reading is AI moderation as a scaling aid for large or lightly staffed courses under human oversight, with equity unverified for sarcasm, indirect language, and minority communication styles.
- **Setter of purposes, not just competencies.** Fagerlund et al. (2026) interviewed 13 Finnish teachers from preschool to grade 9 about why students should learn about and with AI, reading their accounts through Biesta's qualification, socialization, and subjectification. Qualification was the clearest and most concrete purpose, covering AI as both a target of learning and a tool for it; socialization appeared as cultivating favorable stances toward AI and preparing students as AI-savvy future workers; subjectification, self-determined and personally meaningful engagement, was endorsed as important but had no concrete instructional strategies behind it, resting on "discussing and contemplating." The authors propose *informed AI agency*, subjectification at the center with competencies as its foundation, which gives the teaching role a purpose-setting duty: make the "why" explicit so skills acquire context rather than standing as ends in themselves, and complement technical frameworks such as Technological Pedagogical Content Knowledge (TPACK) with sustained attention to educational purpose.
- **Adoption is not the same lever as performance.** Across 200 teachers in North Sumatra, AI use had no direct effect on teacher performance ($\beta = 0.112$, $p = .087$) while organizational citizenship behavior mediated it at $\beta = 0.370$, so it is the extra-role, collaborative work around the tool rather than the tool itself that converts use into performance (Sherly et al. (2027)).

These roles connect teacher work to Distributed Cognition, Situated Learning, Embodied Learning, and Critical Pedagogy, and reframe the teacher as a designer and ethical guide of AI-mediated learning rather than merely a user.

- **AI-supported decisions cluster where behavioral data is available.** Köroğlu et al. (2026) reviewed 27 empirical studies (2016–2025) and identified eight lecturer decision types, finding AI support concentrated on instructional, Feedback and Assessment decisions while curriculum, learning-environment, emotional, ethical and administrative decisions were rarely supported. Learning Analytics Dashboards were the most common system, processing text and log data into behavioral indicators of performance and engagement; Multimodal AI and interaction-based data, agentic systems and cognitive, metacognitive, motivational and affective outcomes were all comparatively rare in the reviewed corpus. The practical reading for instructors is that the decision space an AI tool opens is bounded by the data it displays, so tool selection is also a choice about which teaching decisions are being resourced.

How instructors should adapt their teaching practices to AI

The knowledge base's evidence converges on a set of concrete adaptations:

Design the AI's pedagogical wrapper, not just the tool. The same AI yields large Learning Gains or net harm depending on how the activity is designed around it. Kibar & Ilgaz and the Learning Gains evidence are consistent: the instructor's job is to *design the learning experience*, treating AI as a component within a structured activity rather than the answer engine. Scaffold a student attempt first, then let AI coach — this is the difference between assessment and performance inflation.

Require a Human-in-the-Loop checkpoint. Rather than accepting AI output at face value, teach students to evaluate, correct, and take ownership of AI-assisted work. Fair-use AI literacy frames this as balancing AI's productivity against genuine human flourishing and authorship. Design assignments so AI helps with drafting but the learner remains the agent of evaluation and revision.

Curate AI feedback drafts; do not relay them. Chen et al. (2026) gave 64 Chinese pre-service teachers ChatGPT-assisted feedback on argumentative writing and found that treating the output as draft material rather than finished comment moved critical thinking where teacher-only feedback did not (post-test Cohen's d of 3.74 against 0.25 at pretest, $p < .001$). What the teachers did with the draft is the transferable part: they copied appropriate content at a level similar to their own (28%), expanded it with deeper input (16%), supplied it (16%), revised it (14%), or discarded it entirely (14%), with a further 9% needing correction. The assisted feedback leaned toward modeling (demonstration, 33.1% against 10.9%) and probing (question-closely, 21.5% against 6.0%), and students revised it toward analysis, evaluation, and creation rather than recognition, but six of eight interviewees still reported imprecision and unprofessionalism. The teacher's verification step is what makes the hybrid safe.

Adapt assessment to the age of AI. Move away from tasks LLMs can complete verbatim toward authentic, process-based, and in-person assessments. Assessment scales give instructors a rubric for deciding how much AI assistance is legitimate at each stage, and meta-analytic evidence shows AI can support higher-order thinking when the assessment design demands it.

Protect the conditions for durable learning. Because AI answers make learning look easy, instructors must design to counter the performance-learning gap. Lodge & Loble warn that effortless success with AI can mask the absence of learning; instructors should build in productive struggle, require unassisted demonstration of mastery, and treat AI-supported answers as a starting point, not the finished outcome.

Plan for the delivery medium. Adaptation is not medium-neutral: online teaching with AI multiplies both the opportunities (scalable personalization, always-on support) and the risks (integrity, offloading). Design the AI wrapper as deliberately in online as in face-to-face contexts.(Can AI deliver appropriate support for diverse student profiles? A large-scale evaluation)

Incorporating AI literacy into teaching

AI literacy is not a separate module — it is woven into how instructors design every course. Effective approaches include:

- **Model AI literacy in practice.** Teachers who themselves use, evaluate, and critique AI set the norm for students. AI literacy continua describe the progression from tool fluency to critical evaluation that instructors should scaffold.
- **Teach evaluation and calibration, not just use.** Students need to know when AI is trustworthy and when it hallucinates — Critical Thinking about AI outputs is a core literacy. This connects to responsible use and how AI use is framed for students.
- **Co-construct AI-use norms with students.** Principled approaches to AI education and teacher-authored prompts show that explicit, co-designed expectations work better than punitive rules.

Ensuring academic integrity in the age of AI

Academic integrity with AI is a *design* problem, not a policing problem. Instructors adapt by:

- **Reframing integrity around process and authorship.** Instead of detection, emphasize Academic Integrity as transparent, documented use. Agentic AI and ghost-student research shows the integrity risk shifts when students deploy AI agents on their behalf, so instructors must define what authorship means when the "ghost" is an AI.
- **Using disclosure and framing.** How AI use is framed for students — whether as a crutch or a legitimate tool — shapes whether they disclose it. Transparency norms (e.g., AI-use disclosure) reduce the incentive to hide AI use.
- **Designing out the incentive to cheat.** Authentic, process-based, and in-person assessments (oral exams, portfolios, observed Problem Solving) make outsourcing less attractive than AI-detection tools do. Assessment scales and Authentic Assessment are the constructive alternative to detection arms races.
- **Task-level AI Regulation in Education is how instructors actually govern AI.** Chirikov's (2026) study of 31,000+ course syllabi shows instructors increasingly acting as *task-level regulators* rather than applying blanket rules: they restrict AI for drafting/revising (79% of courses) and reasoning/problem-solving (65%), permit it for editing/proofreading (83%) and study support (80%), and leave ideation/planning most contested (46% permit / 54% restrict). This differentiation — built on which tasks AI displaces versus augments — is a concrete, instructor-

driven alternative to adoption-or-ban policy and gives the teacher-role a central place in policy formation.

- **Sessional staff carry the marking load without the mandate.** Twenty casual academics, some teaching across three or more institutions at once, described detecting misconduct through untrained craft while holding no curriculum or policy authority (Andriamora & Andriamora, 2026).

Connecting teaching to learning design

Teaching and Learning Design are two sides of the same coin — the instructor's daily judgments are the live execution of the designed learning experience. AI tightens this connection:

- **Teachers as learning designers.** LearnAI and teacher-authored prompt design show instructors functioning as designers: specifying the activity, the AI's role, and the scaffolds that structure learning. This is Learning Design in action at the point of use.
- **Learning-design principles govern AI pedagogy.** The same Learning Design principles — clear objectives, aligned assessment, Scaffolding, and Feedback — determine whether AI helps or harms. ISD-Agent-Bench empirically validates that grounding AI design in formal instructional-design models beats theory-free prompting.
- **Design for the teacher's orchestration.** Effective AI learning environments are designed *with the teacher in mind* — the tools human-centered AI provide should reduce teacher workload and augment judgment, not add another opaque black box. When instructors co-design AI learning activities (activity-theory perspectives), adoption and quality both improve.

Relationship to learner identity

Teacher role and Learner Identity are reciprocal faces of the same human process, and AI reshapes both.

- **Teacher identity is a professional identity; learner identity is a learning identity.** The teacher-role page documents how AI reshapes the *work, identity, and agency* of educators — their evolving professional self-understanding (see Laidlaw's framing of GenAI as an identity crisis). Learner identity is the parallel construct for students: who they are and are becoming as learners, in disciplinary, professional, creative, and academic terms.
- **They are causally coupled.** Teachers who experience identity disruption (uncertainty about their professional purpose amid GenAI) are less able to support their students' identity development — a teacher who doubts their role struggles to validate students' emerging sense of self in the same domain. Conversely, teachers who sustain a confident professional identity are better positioned to scaffold students' belonging and authorship.
- **Distinct failure modes.** Teacher identity is threatened by *role obsolescence* and *purpose* (the "what's the point of teaching?" question). Learner identity is threatened by *authorship loss* and *competence* (the "is this really mine / am I good enough?" question). Both are identity-level (not just skills-level) responses to AI.
- **Both are professional-development and pedagogical concerns.** Supporting teacher identity belongs to Educational Development and Teacher AI Competency; supporting learner identity

belongs to Student Experience, Authentic Assessment, and Learner Agency. A well-designed AI-integrated system attends to both — because the teacher's identity is the condition under which learners' identities form.

Teacher Co-Design of Early AI Literacy

- **Teacher co-design in early AI literacy.** Lee (2026) shows that two pre-K and two kindergarten teachers who co-designed the Play With AI (PL-AI) curriculum experienced substantial growth in confidence and pedagogical agency, with co-design fostering curriculum ownership, reflective practice, and meaningful adaptation. This positions teachers as central co-designers — not just implementers — of developmentally appropriate AI literacy curricula, a model with implications for teacher preparation in early childhood AI education.

Teachers Co-Designing AI Learning Resources

- The teacher's role extends to co-designing AI learning resources: teacher-AI co-designed simulations for drone STEM instruction kept GenAI output pedagogically valid and contextually relevant, and teachers are the intended beneficiaries of the Teachers' AI Literacy Scale. Effective GenAI integration increasingly depends on teacher involvement in design.

AI Reflection Systems Should Adapt to Teacher Experience

- **Teacher-facing AI reflection analytics should be expertise-adapted, not one-size-fits-all.** A survey of 100 US K–12 teachers (median split at nine years; binomial tests; 15% choice differences detectable at ~83% power) found systematic preference splits. Less experienced teachers cite lack of reflection time as a top obstacle at 3x the experienced rate (37% vs. 12%, $p < .001$) and want analytics on student disengagement (48% vs. 33%, $p = .028$) and emotions (31% vs. 18%, $p = .036$).
- **The design rule derived from the split is experience-adapted recommendation modes.** Experienced teachers want analytics on improved learning after helping a student (40% vs. 26%, $p = .019$) and on their teaching methods (42% vs. 26%, $p = .012$); their top obstacle is tracking performance (28% vs. 15%, $p = .009$). Design rule: novice mode = structured prompts and engagement analytics; expert mode = flexible longitudinal analysis — a direct argument against uniform dashboards. (How expertise levels shape preferences and reflection needs — towards AI reflection systems for teacher empowerment)

Common Misconceptions

"AI will reduce or replace the pedagogical work of teaching." The expert scenario evidence points the other way. Malyn-Smith et al. (2026) call it the *more-human paradox*: across six 2030 scenarios co-constructed by 20 researchers from 13 countries, AI saturation **intensifies rather than displaces** human pedagogical work. The scenarios describe AI as "the air-handling system of the learning ecosystem" — infrastructure you notice only when it malfunctions. What changes is not the quantity of human judgment required but its object: attention moves from producing materials toward interpreting learners.

“Teacher AI competence means learning the tools.” Tool fluency is the weakest predictor available. In Bai and Hsieh’s (2026) SEM of 898 Chinese university teachers, GenAI-supported teaching innovation depended *less* on isolated AI technological knowledge and *more* on pedagogically and disciplinarily embedded AI competence together with professional identity, both of which partially mediated the outcome. A workshop on features that does not touch pedagogy or disciplinary identity is aimed at the wrong variable — which is why Laidlaw et al. frame faculty GenAI response as an identity question rather than a skills gap.

“Teachers are already co-designers of AI, so the transition is underway.” The aspiration is real; the description is not yet. Wang, Liu and Islam’s (2026) systematic review of teacher–AI co-design of learning tasks finds the co-designer stance **remains uneven**, with the dominant mode still AI as assistant or content generator. Reading that review as evidence of an accomplished shift would hide the gap between the teachers a page like this recommends and the teachers most institutions actually have.

“How a teacher delegates to a chatbot barely matters, since the model does the work.” The delegation pattern is the intervention. In children’s STEAM arts lesson planning, Luo and Tahir (2025) found experimentally that filling content gaps in a *self-outlined* lesson preserved teacher design autonomy while still raising expert-rated plan quality (median 20.5 vs 17.6, p = .002, large effect), outperforming the alternative of letting the model supply the outline. Same model, same task, different division of labor, materially different result.

A Practical Starting Sequence

The evidence supports a specific order of operations for an instructor adopting AI, rather than a list of features to learn.

1. **Write the activity before choosing the tool.** Specify the objective, the student attempt that comes first, and what counts as evidence of understanding. Tools chosen first tend to rewrite the activity around themselves.
2. **Decide the delegation pattern explicitly.** Outline the lesson yourself and let AI fill content gaps, rather than accepting a generated outline — the pattern above with the measured quality difference.
3. **Place the human checkpoint where ownership sits.** Design so the learner evaluates, corrects, and owns the AI-assisted work, and so AI feedback arrives as a draft the teacher curates rather than a comment the teacher relays.
4. **Protect the interpretation time the shift creates.** If attention moves from materials production to reading learners, that reallocated time needs to survive contact with the calendar; if it is absorbed by new administrative work, the promised role change does not occur.
5. **Check whether you are being trained on tools or on pedagogy.** Given the SEM result, prefer professional development that works on disciplinary tasks and identity over feature tours.

Teacher AI Competency

> **Teacher AI competency** — the knowledge, skills, and dispositions teachers need to effectively, ethically, and equitably integrate AI into teaching and learning. It extends beyond technical tool use to include pedagogical integration, assessment literacy, ethical judgment, and the confidence to use AI well. Teacher AI competency is the teacher-side counterpart to AI Literacy, and is developed through professional development. It is central to how the teacher's role is transforming in AI-augmented classrooms.

Questions to Consider

- The page argues the teacher is 'the decisive factor' in whether AI improves learning — that tools only help when teachers can plan for them, scaffold use, and evaluate outputs. Does that match your experience, or do you think the tool itself matters more than the teacher?
- Teacher AI competency spans technical proficiency, pedagogical integration, assessment literacy, and ethical judgment. Which of these do you think teachers most lack, and which is hardest to train?
- The research documents a gap between teachers' self-perceived and actual AI skill. Why do you think people overestimate their readiness, and what would it take to close that gap honestly?
- An intensive professional-development program produced large gains in AI pedagogical skill in the research cited, suggesting technical-pedagogical skill is trainable. If that's true, why do so many teachers still seem unprepared — what's standing in the way?
- If a teacher can 'use AI well,' what does 'well' mean to you — and how would you know a teacher has achieved it rather than just adopted the tool?

Introduction

Teacher AI competency matters because the teacher is the decisive factor in whether AI improves learning. Research consistently shows that AI tools only translate into better outcomes when teachers can plan for them, scaffold student use, evaluate outputs, and integrate them into coherent instruction. The knowledge base's literature examines the *dimensions* of this competency, the *gaps* between self-perception and actual skill, and the *professional development* that builds it.

Nunez-Canal et al. (2026) connect faculty AI competency to student outcomes directly, using human capital and stakeholder theories on a survey of business and economics faculty to argue that universities' investment in faculty competency is not discretionary. - **Prompting training saves time but does not improve materials.** In a preregistered RCT with 204 teachers, Appel, Fervers and Piepenburg (2026) found ChatGPT improved the quality of lesson-preparation materials and cut preparation time by 34%, while prior AI training added a further 21% time reduction without improving rated quality (Appel et al., 2026). Trained teachers wrote longer prompts and iterated less; both routes reached equal quality.

Core competency dimensions

The knowledge base's research converges on several interconnected dimensions:

- **Technical proficiency:** crafting effective prompts for educational objectives, evaluating AI tools for pedagogical fit and safety, and troubleshooting failures in real time. An intensive GenAI PD program documented significant gains across all five AI-PCK components (overall $d = 2.36$), showing technical-pedagogical skill is trainable.
- **Specifying agent workflows:** when teachers configure a chatbot in natural language, the dominant failure is lost intent rather than wrong facts — bots skipped required workflow steps in 53.8% of end-user conversations and omitted expectation setup in 33.4% (Liu et al. (2026)), so writing ordered, explicit steps is a trainable competency dimension of its own.
- **Pedagogical knowledge is the decisive layer.** A cross-level study of secondary AI education (46 teachers, 2,832 students) found technical AI knowledge alone was insufficient — and could even slightly reduce students' perceptions of AI for social good — whereas pedagogical AI knowledge drove students' perceptions and their intention to learn AI. Competency frameworks should therefore weight pedagogical AI knowledge as the pivotal dimension, not a soft add-on.
- **Pedagogical integration:** mapping AI use to learning objectives, designing Scaffolding that supports student Metacognition and self-AI Regulation in Education, and integrating AI into instructional design. AI-TPACK research models how teachers combine technological, pedagogical, and content knowledge through multi-agent workflows, while a five-level teacher-AI teaming framework (transactional → synergistic) captures how GenAI may replace, complement, or augment teacher competence.
- **Assessment literacy:** evaluating AI-generated content and student AI outputs, and understanding how validity shifts when students use AI. This connects to Automated Assessment, AI Detection, and the broader Assessment redesign agenda. For recommendation systems, this extends to judging whether an AI's explanations are genuinely understandable and pedagogically meaningful: Feldman-Maggor et al. (2025) found teachers trusted AI grouping recommendations more when explanations were framed in domain (curricular) language than when they exposed raw model features — a skill for demanding and appraising explanation quality rather than accepting opaque output.
- **Model selection and prompt design as demonstrable skills:** instrumental AI Literacy includes knowing which model to use and how to phrase the task. Jacobsen et al. (2026) had 153 pre-service teachers' lesson-planning goals critiqued by ChatGPT-4, Claude 3 and Gemini Advanced under four systematically varied prompts (N = 240 feedbacks in Study 1, 345 in Study 2), with Feedback rated on nine quality categories. Model choice alone explained 26.9% of the variance in rated quality (18.4% in Study 2) and prompt design added a significant 15.9% (5.7%) on top; the single decisive prompt feature was domain-specific technical language, whose removal significantly lowered quality ($\beta = -0.412$), whereas adding examples and dropping the chain-of-thought instruction made no significant difference in Study 1. Their reading — that subject terminology both unlocks relevant training-data content and frames the request professionally, like

role prompting — plus a rule of thumb to use the most capable current frontier model, makes model choice a didactic decision rather than a technical one.

- **Ethical and critical use:** recognizing bias in AI outputs, protecting student data (Privacy), and ensuring equitable outcomes (Equity). Culturally relevant AI use examines how teachers can use LLMs to diversify materials rather than reinforce dominant norms.
- **Visual representation is its own measurable dimension.** Chen et al. (2026) validated a five-dimension scale for generating, judging and acting on visual representations with 566 teachers across five western Chinese provinces, with subscale alpha from 0.911 to 0.934; it measures reported capacity, with no test-retest and no observation of practice.
- **Ethical responsibility is distributed, not individual.** Across seven national cases teachers are positioned as moral gatekeepers of AI use while lacking institutional and epistemic support, so ethical AI literacy has to extend to critical and political agency rather than technical skill (Raffaghelli et al. (2026)).
- **Confidence and attitudes:** teacher confidence shapes adoption. Adoption research finds confidence, support, and perceived utility drive whether teachers actually use AI, and faculty orientations shape adoption in research and teaching.
- In a five-country survey of 1,405 K-12 teachers, AI readiness predicted positive beliefs about GenAI's instructional value ($B = .59$, $R^2 = .50$) yet predicted *greater* Creativity concern ($B = .18$), and the same predictors explained only 7% and 6% of concern — readiness-building alone leaves concern untouched (Xiu et al. (2026)).

Readiness should be ordered and measured accordingly: the Capability–Decision Model places demonstrated AI capability upstream of attitude and confidence and proposes performance indicators rather than self-report alone — lesson-design tasks, prompt-evaluation tasks seeded with errors, content-validity judgments and classroom artifact rubrics (Mnguni (2026)).

Emotional and moral readiness is a distinct dimension. Vassallo (2026) surveyed the academic staff of a Maltese university (109 respondents) and built an AI Guilt Index ($\alpha = 0.88$) from four moral-emotion items, finding that *anticipatory* guilt outweighed remorse experienced after use: the strongest endorsement was worry that AI use undermines one's credibility (34.9% agreeing), then feeling like one is cheating when using it (25.7%), while post-use remorse drew only 9.2%. The findings that matter for competency frameworks are that non-users reported *higher* guilt than users ($M = 3.25$ vs $M = 2.32$) and that guilt fell as career security rose — early-career academics reported the most ($M = 2.71$) and senior academics the least ($M = 2.03$). Emotional readiness is therefore not captured by skill or confidence measures, and the paper argues competency frameworks should treat guilt and identity concern as normal transitional responses rather than faults to correct.

A stronger version of that reframing holds that GenAI is a threshold concept rather than a skills gap: an autoethnographic account argues faculty anxiety and resistance are constitutive of threshold crossing, so skills-based training fails and principled non-adoption should be respected rather than corrected (Laidlaw (2026)).

Competency shows up as repair, not just prompting. With 7 middle school mathematics teachers rewriting 143 problems, Walkington et al. (2026) coded 415 follow-up prompts: most corrected realism,

readability or mathematical structure, and six caught inappropriate or biased output — teacher judgment operating as monitoring of the generated task rather than as prompt fluency.

The competency gap

A key finding is the **gap between self-reported and performance-based competency**. Research on AI-literacy assessment documents a substantial discrepancy (up to ~40%) between what teachers *believe* they can do and what they can actually *demonstrate* — teachers confident in AI skills often lack foundational prompting and evaluation abilities. This motivates **performance-based assessment** of teacher competency rather than reliance on self-report, and connects to calibrated self-assessment. A national survey of 2,586 Nigerian secondary teachers measured the two sides with separate instruments — moderate AI awareness (M = 3.13 of 8) against lower AI pedagogical skill (M = 2.47 of 5) — with early- and mid-career teachers reporting higher skill than experienced colleagues (Olurinola et al., 2026).

Readiness is the most-documented obstacle in the mathematics literature. A review of 54 mathematics-education studies found technological–pedagogical integration and teacher readiness the most frequently reported challenge (38 of 54), ahead of assessment validity and integrity (26) and overreliance (24) (Manto et al. (2026)).

The gap is not only between perceived and actual skill but in the *breadth* of what teachers know: a national survey of 2,018 Ukrainian secondary educators found 84% reported using AI in professional practice while only 11% could name a specialized AI service beyond ChatGPT (Marienko, Markova & Semerikov (2026)). A second narrowness shows in what teachers volunteer rather than what they can name: 53 in-service teachers tagging their own classroom cases against the OECD AI Literacy Framework described 43 AI-literate practices against only 10 failures (Wang et al., 2026). Their competency selections clustered on practical judgment (evaluating AI outputs, N = 38) and rarely reached societal bias (N = 5), ethical alignment (N = 6) or AI's energy use (N = 9).

A 132-teacher survey in Indonesia found near-universal acceptance alongside thin mechanistic understanding: 96.2% endorsed AI use by teachers, yet only 4.6% named tokenization or decoding and 21.5% believed ChatGPT searched a database or the internet (Aji et al. (2026)). A favorable attitude is not evidence of a workable mental model of the tool.

The gap is visible in the artifact as well as in the self-report. A cross-institutional faculty collaboratory in teacher preparation, in which teacher educators designed AI into their own methods courses, reported that candidates could produce polished AI-assisted lesson plans while being unable to explain why a plan fit the learners and the standards, since the plan itself says nothing about the reasoning behind it. Grading the justification rather than the product is one response. The pedagogies-of-practice frame suggests another, treating rehearsal as an approximation of practice: AI-mediated rehearsal with structured post-rehearsal feedback raised candidates' use of probing and exploring questions, yet candidates' own judgments of their performance still diverged from what observers recorded.

A falling self-assessment after training can signal learning rather than loss. In a six-month Intelligent-TPACK professional development program with 64 Hong Kong university teachers against 61 controls, overall AI competency rose by about half a standard deviation (Cohen's d = −.521), yet some teachers in both groups scored lower at post-test than at pre-test (Tan, Cheng & Ling, 2025). Interviews attributed the declines to a shift from unconscious to conscious incompetence — the recalibration the Dunning–Kruger

effect predicts — rather than to lost skill. The authors conclude that pre-post self-report understates an intervention, because part of the gain arrives as a downward correction in the instrument itself.

The gap can invert across the pipeline. In postgraduate medical education, twelve physicians who lead AI curriculum work expected residents to become more fluent with AI than many of their teachers, and proposed co-learning and co-teaching rather than a one-way upskilling of faculty (Bursic et al. (2026)). The same interviews described informatics units not yet mature enough to lead curriculum development, which locates the constraint in institutional capacity as well as individual skill.

The gap also shows up as non-participation. Watson & Rainie (2026) surveyed 1,057 US college faculty in late 2025 and found 26% do not use generative AI tools at all, with a third choosing not to use them for teaching and non-use concentrated in the arts and humanities (40%). The institutional side of the gap was larger than the individual one: 68% said their schools had not prepared faculty to use generative AI for teaching and mentoring, and faculty named colleagues' resistance (82%) and unfamiliarity (83%) as the leading obstacles to departmental adoption — a picture in which capability-building, peer norms and policy all have to move together.

Pre-service training largely sidesteps the ethical dimension of the competency. A systematic review of AI in initial teacher training for pre-service primary mathematics teachers (Pinto et al. 2026, 11 studies selected from 341 records) found the interventions concentrated on short-term technical and pedagogical gains, with nine of the eleven running brief interventions spanning one to six sessions, and reported that ethics was addressed in only three of the eleven studies. The competency frameworks name ethical judgment as a dimension; the pre-service literature meant to build it rarely teaches or measures it.

- **Seven competence clusters, with ethics the weakest link.** A thematic synthesis of 78 studies yields clusters for prompt engineering, critical evaluation of AI outputs, ethical awareness and bias detection, pedagogical-content alignment, conceptual AI literacy, human oversight and reflection. Prompt engineering was the most consistently documented and behaves as a **developmental spectrum** rather than a single skill, which led the reviewers to argue it is best understood as pedagogical reasoning conducted through a new medium — the prompt as an externalized design decision. Ethical awareness was the **weakest documented competence** in the pre-service studies (Spyropoulou & Kameas, 2026).
- **Teachers overestimate their own evaluation skill.** Beyond the finding that only **38.3% of AI-generated learning objectives met all quality criteria without revision**, pre-service teachers **systematically overestimate their ability to evaluate chatbot output** — which the reviewers read as a possible perceptual rather than declarative deficit. This is why they argue competence should be assessed through performance artifacts (lesson plans, decision logs, micro-teaching) rather than self-report: the unreliability of self-assessment is demonstrated in the very literature the training is meant to address.

Professional development that works

The knowledge base's PD literature identifies effective approaches:

- **Intensive, theory-grounded programs:** An intensive GenAI PD program with 163 teachers/pre-service teachers produced significant gains across all AI-PCK components, with pre-service

teachers benefiting most. Self-determination-theory-based PD shows need-supportive training improves teachers' AI literacy, attitudes, and engagement while reducing anxiety.

- **Design-based and integrated approaches:** DBR-based GenAI literacy training addresses the overemphasis on technical knowledge and pre-GenAI tools; integrative, developmental frameworks and social-emotional competency integration broaden literacy beyond pure technique.
- **Inquiry and authentic practice:** AI-supported inquiry models build AI literacy and authentic performance in pre-service teachers.
- **Context-specific readiness:** The EPIQ-AI readiness framework emphasizes that faculty readiness is a sociotechnical issue requiring alignment of faculty capacity, AI Governance, and quality assurance.
- **Support must be differentiated by experience and AI proficiency.** Choi et al. (2026) found that how teachers actually interact with AI in lesson design depends on the *interplay* of teaching experience and AI proficiency, not either alone. Experienced teachers with high AI proficiency critically adapt AI output to context (re-prompting, elaboration), whereas novices — even technically fluent ones — tend to accept AI responses directly and rarely consider students and context. This argues for profiling-based PD: response-evaluation checklists and prompt templates for novices, and hands-on skill-building for experienced teachers with lower AI proficiency.
- **The time benefit itself follows experience and confidence, not only support design.** In Roy et al.'s (2026) trial of an AI lesson assistant, the workload reduction was larger for teachers with lower subject-knowledge confidence, lower pedagogical knowledge, less time in the profession, or higher confidence with technology. Proficiency and confidence are therefore part of the intervention's effect, not only part of its take-up.

Belief configuration is a second profiling axis: among 40,680 teachers in TALIS 2024, the same non-use status masked opposite barriers — 83.3% of the Indifferent profile cited pedagogical reservations while 66.2% of Measured Endorsement cited insufficient knowledge and skills (Fang & Jin (2026)). AI-related professional learning tracked profile membership more consistently than age or attainment.

- **Teachers do not share one conception of AI.** A phenomenographic study of 16 Danish higher-education teachers found three conceptions of teaching-with-AI and three of learning-with-AI, so a single workshop model reaches only part of any faculty group (Stenalt (2026)).
- **Co-design and pedagogical prompt literacy are competencies, not add-ons.** A systematic review of teacher–AI co-design of learning tasks (Wang, Liu & Islam 2026, 28 studies) finds the dominant collaboration mode is AI as assistant/content generator, and locates a gap in teachers' fuller co-design and dialogic partnership capacities. Talebzadeh (2026) shows PD that pairs technical AI training with pedagogical reasoning — building "pedagogical prompt literacy" (encoding PCK into prompts) — is what lets teachers turn AI output into effective differentiated group activities.
- **Structures that build competency, rather than lists of it.** Perl-Nussbaum and Finkelstein (2026) ran a six-session biweekly faculty learning community in a large public R1 physics department — nineteen faculty across the series, about ten at each meeting — where every session opened on local data, moved to small-group testing of AI against real anonymized student homework, and closed in collective discussion, and it produced a five-entry shared repository rather than a training

package. Assessment literacy can be built the same way through a design tool: in Paula et al.'s (2026) pilot, eight experienced STEM and Health course coordinators grew their assessment literacy by critiquing a custom GPT's assessment drafts against disciplinary standards, even though the outputs repeatedly missed disciplinary context, ignored topic sequencing, and in one case carried fabricated references through repeated prompting. All eight kept academic judgment with themselves and refused end-to-end automation, which makes structured critique of generated drafts the development mechanism rather than tool training.

- **Short sessions can move acceptance without moving adoption.** Mesenhöller and Böhme (2026) evaluated a three-hour INSIGHT session with 100 German teachers and found perceived usefulness and perceived ease of use both rose significantly (usefulness $t(99) = -3.24$, $p = .002$, $d = .32$; ease of use $d = .25$) while behavioral intention to use AI-based technologies for differentiation did not change. The authors note their baselines were already favorable, so a ceiling effect is plausible. The reading for PD design is narrow but useful: a short session can shift how teachers judge AI tools without shifting whether they plan to use them, which is the kind of change that needs follow-through rather than a one-off event.
- **Instructors prefer fluency but attribute learning to scaffold.** Across 41 instructors, a GPT-4o baseline was preferred overall (21 vs 13) yet the fine-tuned three-step model (identify, explore, develop) was more often credited with learning (18 vs 13), and the two judgments agreed only 39% of the time (Molnar et al. (2026)).
- **Institutional support:** professional development must be paired with institutional infrastructure (policy, institutional change) for sustainable adoption.
- **Authoring tools do not guarantee pedagogical fidelity.** Riahi et al. (2026) studied 27 middle school teachers configuring educational chatbots in professional-development workshops, analyzing focus groups alongside configuration and interaction logs. Teachers treated the chatbot as an instructional scaffold bounded by teacher-defined rules, yet log-based alignment between intent and behavior was stronger for responsiveness (88.9%) and persona (81.5%) than for rules (70.4%) and purpose (59.3%). Configurable controls alone do not carry pedagogical intent into behavior, so expressing, testing, and refining a chatbot's pedagogy is itself a competency the authoring tooling has to support.

A design-based counterexample treats competency as situational rather than a rung on a ladder. Eyal's 2025 design-based study with 22 higher-education teacher educators had participants examine five published assessment frameworks and co-design an alternative organized around three inter-related axes: context fit (infrastructure, socio-cultural factors, local needs, developmental stage), professional needs (discipline, pedagogy, leadership, support), and dynamic development. The model rejects fixed competency levels and allows non-linear progression, and it ships with a 20-item reflective self-assessment questionnaire rated 1 to 5. Its validation is qualitative only, with no quantitative reliability testing, so it stands as a design contribution rather than a validated instrument. - **Meta-analytic estimate.** Guo et al. (2026) pooled 212 effect sizes from 34 studies and estimate teacher AI-literacy PD at $g = 0.76$ (95% CI [0.50, 1.02]), strongest

for skills (g = 0.91) and weakest for attitudes and values (g = 0.61); correcting for apparent publication selection lowers the estimate to about g = 0.49.

- **Attendance predicts gains where the feeling of participating does not.** In the same six-month program, attendance rate predicted the competency gain (β = .407, p = .001) while self-perceived participation did not (β = .049, p = .692), and discipline, teaching experience and professional title explained little; the authors read attendance as behavioral investment and perceived participation as surface-level engagement (Tan, Cheng & Ling, 2025).
- **Values lag skills in a domain-specific program too.** In a year-long Hong Kong program with 30 English teachers, knowledge of Multimodal AI assessment strategies rose from 3.13 to 4.15 out of 5 (partial $\eta^2 = 0.571$) and competence in supporting students from 3.05 to 3.98 (0.482), both significant, while every value subdomain stayed statistically flat under a Bonferroni-corrected alpha of .006. The teachers attributed the gains to in-school co-planning and cross-school cluster meetings rather than the workshops alone (Jiang et al., 2026).
- **Microlearning can develop university teachers' AI competence.** Cechovsky (2026) refined two Vocational Education and Training modules across two online group discussions into five design principles — clear structure and orientation, guidance and navigation support, segmentation and modularization, multimodal presentation, and learner activation — and found platform navigation and locating modules the main practical barriers.
- **Intention to adopt runs on need satisfaction.** In a structural model of 146 teachers, competence need satisfaction predicted intention to use GenAI through intrinsic motivation and engagement in professional development (indirect 0.233), while autonomy and relatedness satisfaction did not (Yuan et al., 2026).

Teacher AI competency and the transforming teacher role

As AI takes over routine instructional and assessment tasks, the teacher's distinctive contribution shifts toward orchestration, judgment, and relationship: deciding when and how AI is used, scaffolding student agency and critical use, ensuring equity, and providing the social and emotional support AI cannot. This reframes teacher competency around human-in-the-loop oversight, ethical judgment, and supporting self-regulated learning — connecting to Teaching and guarding against over-reliance.

Implications for AI in education

- **Assess performance, not just self-report:** teacher competency should be evaluated through demonstration, given the documented self-report gap.
- **Train the full competency, not just tools:** PD should build technical, pedagogical, assessment, and ethical dimensions together, grounded in learning theory.
- **Build confidence alongside skill:** attitudes and Self-Efficacy shape adoption, so PD should reduce anxiety and build confidence through authentic, supported practice.
- **Support the institutional layer:** sustainable teacher competency requires aligned policy, governance, and capacity, not isolated training.

- **Teacher digital competence for GenAI curriculum design.** Guillén-Gámez (2026) validate a TAM-based diagnostic instrument with 434 in-service teachers; behavioral intention was the main predictor of digital competence for using GenAI in curriculum planning, with self-efficacy as a root driver.

A Psychometric Instrument for Teacher AI Competency

- A psychometric study developed the Teachers' AI Literacy Scale (TAILS) to measure AI literacy specifically within language teacher education, operationalizing the ED-AI framework's six dimensions. The instrument's development fills a gap in assessments that target students or general users, supporting the measurement of teacher AI competency.

The instrument landscape itself has since been reviewed. Zainal, Mohd Matore and Maat's 2026 systematic review of teacher AI literacy measurement tools appraised 33 instruments published between 2019 and 2025 and found the field methodologically monotonous: 31 (93.9%) are self-report scales of perceived confidence, only two (6.1%) test knowledge objectively, and none use performance-based tasks. Internal consistency was the strongest quality domain (28 of 33 at Grade A) and fairness the weakest, with five instruments (15.2%) reporting measurement invariance or differential item functioning evidence. Content also lags the technology, since 29 instruments (87.9%) target general AI concepts and only four (12.1%), all from 2025, address generative AI.

Common Misconceptions

- **"Prompting training makes teachers' materials better." Prompting training buys time, not better materials**: in a **preregistered RCT with 204 teachers**, Appel, Fervers and Piepenburg (2026) found ChatGPT improved **time spent** while the material quality did not follow. The efficiency gain is real and it is not the quality gain.
- **"When teachers configure a chatbot, the failure is factual error." When teachers configure a chatbot in natural language, the dominant failure is lost intent rather than wrong facts** — bots **skip** the step the teacher meant. Instruction-following fails structurally rather than factually.
- **"Technical skill is the decisive layer." Pedagogical knowledge is the decisive layer**: a cross-level study of secondary AI education Shen et al., 2026. The competence that determines the outcome is the one most training programs under-invest in.

Learning Design

> **Learning Design** (also known as *instructional design*) — the systematic process of creating effective learning experiences through the analysis of learning needs and the design, development, implementation, and evaluation of instructional materials and activities. AI is transforming learning design by automating content creation, enabling adaptive learning paths, supporting data-driven iteration, and augmenting — rather than replacing — the instructional designer's role.

Questions to Consider

- Think of a course or lesson you have experienced or designed. Where did 'what to teach' (curriculum) end and 'how to teach it' (learning design) begin — and how did the two interact?
- A common assumption is that better AI fluency automatically produces better educational content. The page counters this with evidence that explicit pedagogical structure — not just AI fluency — is what determines learning effectiveness. Where have you seen impressive output that failed to teach?
- If an AI tool can generate a full course from a prompt, what human decisions become more important rather than less? The page argues AI augments rather than replaces the instructional designer's role — what would that augmented role look like?
- Some instructional-design models like ADDIE are used as rigid, linear steps. But the page treats them as iterative, flexible planning heuristics. When might following a process too literally undermine good design?
- The page shows that pedagogically grounded prompting — for example, a five-step framework based on learning theory — significantly improved higher-order outcomes. If you were building an AI tutor, what would you encode in an explicit design layer so its teaching strategy stays traceable and reproducible?

Introduction

Learning design bridges AI capabilities and effective pedagogy. Where Curriculum Design addresses *what* to teach at the program level, learning design addresses *how* to teach it at the course and lesson level. The articles in this knowledge base explore both AI as a tool for learning designers and learning-design principles for building effective AI tutoring systems.

What that design work involves in practice is itself an empirical question. Tang et al. (2026) coded 1,378 designer-chatbot turns from five novice learning designers working with a chatbot embedded in a design tool, and found the dialogue clustered on intended learning outcomes and pedagogical approach rather than content generation. Designers returned to outcomes repeatedly as an alignment check while turning curriculum components into concrete tasks, and the assistant's role shifted across phases, from clarifying terms to supporting task design to running a verification pass before a deadline. Design support, on this evidence, is less about producing material than about keeping design intent coherent.

Learning analytics and generative AI support different parts of design: across 11 focus groups at one Australian university, analytics discourse co-occurred most with context and course-level Problem Solving (0.32), while GenAI discourse centered on assessment design (0.26) and designing for student self-determination (0.15) (Claassen et al. (2026)).

Key research themes

AI-assisted content creation is the most directly transformative application. **Curriculum as Code** presents a six-phase architecture integrating Generative AI with LaTeX and Python to automate STEM materials creation, validated across 8 modules and 28 project contexts with student quality ratings of 8.5-9.9/10. **Instructional Agents** uses a multi-agent framework structured around the ADDIE model, with role-based agents (Teaching Faculty, Instructional Designer, Course Coordinator) collaborating to generate complete course materials. **CourseBlueprint** provides a structured pipeline for adaptive pedagogical video generation grounded in course corpora, demonstrating that explicit pedagogical structure — not just AI fluency — is essential for educational content generation. Generative AI platforms can also embody learning-design principles in the content they produce: an AI-powered platform for generating mathematical modeling problems combined established design principles with retrieval-augmented generation, developed through the ADDIE approach to produce pedagogically grounded tasks and recommendations that conventional content generators lack. Yet the payoff of such AI-assisted content and lesson generation is mediated by the teacher's own expertise: Choi et al. (2026) found that experienced teachers critically adapt AI-generated lesson ideas to students and context (re-prompting and elaborating on output), whereas novices tend to accept AI suggestions directly — so the pedagogical value of AI content tools depends on the teacher's experience and AI proficiency, not the tool alone. A systematic review of teacher–AI co-design of learning tasks (Wang, Liu & Islam 2026) confirms the pattern at scale across 28 studies (2015–2025): GenAI is used mainly for lesson planning, prompt generation, and creative ideation, and the dominant collaboration mode is AI as assistant/content generator rather than a fuller co-designer — with efficiency, responsiveness, Creativity, and equity recurring as affordances. Talebzadeh (2026) sharpens the teacher-expertise finding for group activity design: experienced teachers produce richer, more synergistic, better ZPD-aligned role architectures in AI-designed cooperative activities than novices regardless of AI familiarity, framing "pedagogical prompt literacy" as the lever that turns AI output into effective differentiated group learning.

The Aila trial puts a planning-time number on that pattern. Teachers in its randomized primary schools spent 2.51 hours a week preparing lessons with the tool against 3.32 hours without it, yet the median teacher planned only 21% to 40% of lessons from scratch, which is the case a from-scratch tool addresses (Roy et al., 2026).

Where generated materials fall short is curriculum fit: seven math teachers rated AI-generated Productive Failure problems close to human ones on overall quality (M = 17.19 vs 17.43 of 25) but lower on curriculum alignment (M = 2.57 vs 3.29), so generated problems still needed editing for length, reading level, and visuals (Rhaimi et al. (2025)).

Prose quality is the other shortfall, and it is not the same as reading level. Clark et al. (2026) show that model output over-uses constructions with known comprehension costs — low-frequency n-grams, stacked nouns, denominal verbs, long dependencies, reduced object relatives — compared with meaning-preserving

paraphrases and human baselines, so AI-written explanations and readings need an editing pass that a grade-level formula will not catch (Why is AI-generated language so hard to understand?).

Pedagogically grounded AI tutoring applies instructional design principles to AI system design. **Brisson et al.** built a didactically-driven Large Language Models (LLMs) teacher assistant where tutoring strategy is encoded in an explicit external layer — making content selection and didactic structuring traceable and reproducible, directly addressing opacity concerns in Rethinking Scaffolding in LLM Tutors: The Interactional Mismatch Between Benchmarks and Real-World Deployments. **Hou et al.** demonstrated that a five-step prompting framework grounded in Generative Learning Theory significantly improved higher-order cognitive outcomes, showing that instructional guidance — not just AI access — determines learning effectiveness. Both connect to Scaffolding and Intelligent Tutoring.

Frameworks and evaluation provide structured approaches. **WIP: Bridging the Gap Between Instructional Design and Pedagogical Use: A Framework for Mathematics Educators** and **CoTAL** demonstrate human-in-the-loop design principles. **Generative AI (GenAI) as a mindtool that supports generative learning (GL)** positions AI as a "mindtool" — a cognitive partner that extends rather than replaces learner thinking — directly applying instructional design theory to AI integration. **LUDIA** applies Universal Design for Learning principles to create an accessible AI thought partner for educators, connecting instructional design to Inclusive Learning. **AIRIS** (Activate–Inquire–Reflect) is a task-structuring framework for cognitively activated AI use that bounds the AI's contribution so that prediction, interpretation, and evaluation remain the learner's — an AI-specific adaptation of inquiry cycles grounded in Self-Regulated Learning, Cognitive Load Theory, and Human AI Collaboration. Complementing these design frameworks, the Dohn et al. (2026) taxonomy offers a *classification* rather than a design method: six categories (Learning Objective, Content, Representation Format, Epistemic Engagement, Social Design, Artifacts) that let designers and researchers describe, compare, and imagine GenAI learning activities by making explicit why, what, how, with what, and with whom learners engage GenAI — built as a boundary object through postdigital dialogue. Smart-classroom frameworks extend this to teacher education: Zhu, Liang, Mao, and Wang (2026) propose a three-dimensional framework for smart education — learning effectiveness, information and communication technology (ICT), and classroom organization — and instantiate it in a mathematics M.Ed. course that integrates automated scoring, personalized recommendations, and multi-AI feedback across pre-, in-, and post-class stages. A quasi-experiment showed significant gains in students' ability to formulate precise, professionally grounded instructional objectives, yielding the transferable **D-T-E Model** (Disciplinary Demand–Technological Empowerment–Evaluation Loop) — discipline-specific guidance for teacher educators moving smart-education concepts into practical instructional design practice.

Design for reach. Halani's seven-lever framework asks of each course setting which ones still operate when the student is alone with AI; structural moves such as changing what the grade certifies, or tasks that cannot be completed without the thinking, reach further than telling students that process matters (Halani, 2026).

Constrain the tool to protect the thinking. A nine-week argumentative-writing design sequenced teacher-delimited chatbots that ask questions and refuse to generate student prose, and four high-school students moved from passive AI consumers to evaluators who pushed back on outputs — strategic constraint, not unrestricted generativity, tracked the gains (Konradt, Boote & Taub (2026)).

Rubric-guided prompting as a design lever. Yaşar et al. (2026) demonstrated that the rubric functions as a mediating interface between human pedagogical intent and machine inference: treating assessment criteria as revisable design artifacts — rather than fixed instruments — and iteratively co-refining them with the LLM raised LLM–human agreement on student design work from 54.75% to 81.25%. Rubrics engineered for LLMs must balance precision and flexibility — too vague invites free interpretation, too rigid reduces the model to pattern-matching — and role-aware prompting (instructor, peer reviewer, grant reviewer) yielded distinct evaluative feedback. This positions rubric engineering as a concrete learning-design practice for shaping AI evaluation behavior, with human-in-the-loop oversight remaining essential.

AI agents for instructional design extend the field into agentic AI. **ISD-Agent-Bench** is the first standardized, theory-grounded benchmark for evaluating LLM-based instructional design agents. Its 25,795-scenario Context Matrix (51 contextual variables × 33 ISD sub-steps from ADDIE) shows that agents grounded in classical ISD frameworks (ADDIE, Dick & Carey, Rapid Prototyping ISD) outperform theory-free agents, empirically validating that instructional design is a structured discipline rather than a generic prompting task. Agents are not only *builders* of designs but also *critics* of them: Wang, Mitchell & Piech (2025) use a single autonomous web agent that navigates a multi-step online lesson like a student to evaluate a learning design *before* real learners engage. Its description of the student experience predicts where novices will drop out and surfaces actionable design feedback, outperforming every baseline and even a simulated cohort of students on a global CS1 course. This frames pre-launch, agentic evaluation as a low-cost complement to human design iteration. **Enabling multi-agent systems as learning designers: applying learning sciences to AI instructional design** and **Instructional Agents** explore multi-agent frameworks that orchestrate role-based agents around instructional-design models, while **AI-TPACK** examines how teachers and agents jointly apply technological-pedagogical-content knowledge. This work connects instructional design to benchmarking, AI Ed Evaluation, and the design of curriculum at scale.

Connections to related concepts

Learning design is the bridge discipline of AI in education — it connects Curriculum Design (what to teach) with Scaffolding (how to support learners), Educational Development (how to prepare educators), and Generative AI (the tools themselves). It is tightly coupled with Teaching because AI tools reshape what learning designers and teachers do, and with AI Literacy because effective AI integration requires educators to understand AI capabilities and limitations. Design work ultimately resolves into an *order of activity*: pedagogical patterns catalogue the tested orders of moves, so a designer can decide where in a lesson AI belongs rather than only what to include. The learning sciences are the research field behind these principles: where this page covers the professional practice of creating learning experiences, the learning sciences study that practice and its designs empirically and generate the cognitive, motivational and social principles that learning design then operationalizes.

Co-design and what must stay human

Co-design is the part of design practice where the relational work is least substitutable. Zeivots et al. (2025) treat GenAI as an unreliable collaborator rather than a drafting tool, and build a three-phase sequence around that unreliability: the model provokes, pluralises and facilitates, while the group interrogates its framings, generates counter-narratives and holds the deliberation itself. What stays human is the negotiation — which

voices are missing, which framing the group adopts, and what the shared understanding will be. The article is a collective forum of nineteen authors with no experiment, so the sequence is a proposal about practice rather than a tested method.

How learning design determines learning gains

Learning design is the lever that decides whether AI produces learning gains or merely AI-inflated performance. The knowledge base's evidence is consistent on this: **the same AI tool yields large gains or net harm depending on how the learning experience is designed around it.** Hou et al. showed that a five-step prompting framework grounded in learning theory significantly improved higher-order cognitive outcomes, while access to AI alone did not; mindtool and AIRIS frameworks preserve the learner's cognitive work so that durable gains (rather than task-efficiency) result. Design choices that protect Learning Gains — scaffolding that requires a student attempt, Formative Assessment with unassisted outcome measures, and pedagogical structure that keeps the learner the agent — mirror the field's finding (see Learning Gains) that AI is a strong gain when it coaches and a harm when it answers. Conversely, poorly designed AI-integrated lessons fall prey to the performance-learning gap, where apparent success masks no learning.

Practical guidance for designers and developers

For instructional designers, course developers, and engineers building AI-assisted learning experiences, the knowledge base's findings translate into actionable practice. One boundary is worth marking before the practices themselves: learning design as this page describes it is the design of a course for a known cohort, whereas the same principles baked into a product that many courses — taught by people the designer will never meet — will use are the work of Educational Technology Developers, where defaults, configurability and documentation carry pedagogical weight:

Ground AI generation in a structured instructional model. AI content is only as good as the pedagogical structure behind it — explicit structure, not AI fluency, determines quality. Design around a recognized model (ADDIE, Dick & Carey, rapid prototyping) and encode pedagogical decisions explicitly rather than relying on the model to infer them.(CourseBlueprint: A Structured Pipeline for Adaptive Pedagogical Video Generation Grounded in Course Corpora)(ISD-Agent-Bench: A Comprehensive Benchmark for Evaluating LLM-based Instructional Design Agents)(A didactical-driven teacher assistant for a dimensional modeling course)

Adopt a principle-level framework as well as an instructional model. A course-level model structures one design; a published framework sets the criteria that many designs should satisfy. An example worth reading in full is Digital Promise's *Powerful Learning with Emerging Technology*, which organizes its guidance under three principles — Evidence-Based, Learner-Centered, Skill-Building — each expanded into practices and strategies, and attaches Privacy, explainability and fairness to particular practices as safety obligations rather than optional extras.(Powerful Learning with Emerging Technology) **Match the AI configuration to the task, not to sophistication.** Nalyvaiko (2026) distinguishes four layers — prompt, context, harness, and verified loop — and applies a minimally sufficient layer principle: use the least complex configuration capable of a verifiable result, since added orchestration brings coordination, verification, privacy and comprehension costs.

Use role-based multi-agent workflows for content production. Instead of one generic prompt, orchestrate distinct agents/roles (teaching faculty, instructional designer, course coordinator) that collaborate through a defined pipeline — this mirrors how real course teams work and yields more complete materials than a single prompt.(Instructional Agents: Reducing Teaching Faculty Workload through Multi-Agent Instructional Design)(Enabling multi-agent systems as learning designers: applying learning sciences to AI instructional design)

Provide instructional guidance, not just AI access. Whether learners interact with AI directly or with AI-generated materials, guidance built on learning theory (e.g. a stepwise prompting scaffold grounded in generative-learning principles) drives higher-order outcomes; access alone does not. Design the learning activity around how the mind learns, and treat AI as a cognitive "mindtool" that extends thinking rather than replacing it.(The Role of Instructional Guidance in Generative AI-Assisted Learning: Empirical Evidence from Construction Engineering Education)(Generative AI (GenAI) as a mindtool that supports generative learning (GL))

Model forgetting, and schedule review where decay is worst. G4L represents knowledge decay with an Ebbinghaus forgetting curve driven by elapsed time and repetitions, and prioritizes the units most vulnerable to decay rather than re-serving whatever was scored most recently (Csépányi-Fürjes & Kovács, 2026).

Fowlin et al. (2026) add an operational move for deciding where AI enters: unbundle an activity into the components best done independently and those best coupled with AI, keeping the educator's judgment central to the split (Fowlin et al. (2026)).

Make content traceable and reviewable. Let a human designer review and correct AI output before it reaches learners, and structure AI generation so the pedagogical rationale (why this content, in this order) is inspectable — addressing both quality and the opacity concerns that undermine Trust-generated instruction. (WIP: Bridging the Gap Between Instructional Design and Pedagogical Use: A Framework for Mathematics Educators)(CoTAL: Human-in-the-Loop Prompt Engineering for Generalizable Formative Assessment Scoring and Feedback) - **Review AI-generated media at the script stage, not after synthesis.** PedaCo puts educator review on the script — where pedagogical errors are cheap to fix — before anything is rendered; rated instructional validity rose from 3.07 to 3.86, while the automated post-synthesis layer improved only two of five dimensions (Kim, Baek and Kwak (2026)).

Design for Accessibility from the start. Apply UDL principles when building AI tools and AI-generated materials so they serve diverse learners, rather than retrofitting accessibility after the fact.(LUDIA: A Design and Evidence Statement)

Plan for the delivery medium. Instructional design for online teaching and learning is not a neutral translation of in-person design — the medium changes what scaffolding, assessment, and interaction are viable, and AI multiplies both the opportunities (scalable personalization, always-on support) and the risks (integrity, cognitive offloading) designers must plan for. Design the AI's pedagogical wrapper as deliberately in online as in face-to-face contexts.

Evaluate against a benchmark, not vibes. If you're building an instructional-design agent, evaluate it against a standardized, theory-grounded benchmark (e.g. ISD-Agent-Bench) so you can measure whether

grounding in a real ISD framework actually improves output over a generic LLM.(ISD-Agent-Bench: A Comprehensive Benchmark for Evaluating LLM-based Instructional Design Agents)

- **AI is reshaping instructional design practice.** Kibar & Ilgaz (2026) systematically review 28 studies (2020-2025) and find AI assists designers with content generation, templates, and personalization, and is conceptualized as a co-worker/collaborator/partner rather than just a tool — though pedagogical alignment and practitioner readiness remain challenges.
- **The documented activity is concentrated in one phase of the cycle.** In a review of 78 studies of AI-supported instructional design, Design-phase activity appears in **74 of 78 studies (95%)** and Development in 44 (56%), while Analysis reaches only 11 (14%), Evaluation 10 (13%) and Implementation 7 (9%) — and **no study examined AI support across the complete ADDIE cycle**. The cycle is an aspiration the evidence base does not cover, which matters for anyone being sold "AI-powered course development" as an end-to-end capability (Spyropoulou & Kameas, 2026).
- **Three AI roles, hierarchically distributed.** *Generative* use — AI producing design content at the educator's direction — dominates at **96% of studies**; *scaffolding* use, where AI structures the designer's own reasoning, appears in 35%; *evaluative* use, where AI assesses artifact quality, in 21%. The field is overwhelmingly using AI to make things rather than to interrogate its own design decisions, which is the opposite of the critical-friend configuration the review singles out as educationally promising.

Common Misconceptions

- **"AI lesson planning returns time to teachers."** Planning time did fall, from 3.32 hours a week to 2.51 with the tool, but **the median teacher planned only 21% to 40% of lessons from scratch**. Time was saved and the planning did not become substantially more thorough — the saving accrued rather than being reinvested.
- **"Co-design with AI is well evidenced."** A systematic review of teacher-AI co-design of learning tasks **confirms the pattern at scale across 28 studies**, which describes a consistent practice rather than demonstrating superior outcomes.
- **"The rubric is a fixed input."** The rubric functions as a **mediating interface between human pedagogical intent and machine inference**: treating assessment criteria as **revisable** is what lets the instrument carry the educator's intent. A fixed rubric transfers the machine's default framing into the assessment.

Educational Development

> **Educational Development** (also known as *faculty development*) — the processes, programs, and institutional supports that help educators develop the skills, confidence, and professional identity to teach effectively with AI. Educational development spans individual training, curriculum redesign, institutional policy change, and the cultural work of making sense of what GenAI means for the academic profession.

Questions to Consider

- If faculty in the same department describe AI as a human-like 'assistant' on one hand and a mere 'tool' or 'search engine' on the other, can a training program really succeed before those underlying mental models are surfaced? What might happen if development skips that step?
- Educational development is often treated as closing a skills gap — teach faculty the tools and they'll adopt them. But some research frames GenAI integration as an identity-level change ('what's the point of teaching in a GenAI world?'). Which framing do you think is more accurate, and what different actions does each one imply?
- Readiness frameworks like EPIQ-AI split faculty readiness into epistemic, pedagogical, institutional, and quality-and-compliance domains. If readiness is a sociotechnical alignment problem rather than an individual skills gap, what does that say about where a lone 'AI workshop' is likely to fall short?
- When have you felt your own assumptions about a new technology surfaced and shifted — through discussion, metaphor, or shared language rather than instruction? What role do you think shared language and metaphor-analysis play in helping educators make sense of AI?
- Consider a low-tech 'metaphor workshop' where faculty, staff, and students articulate whether AI feels like a Swiss army knife, a helper, a black box, or a competitor. Could surfacing fears (including the fear that AI will replace teaching roles) do more for adoption than more technical training?

Introduction

Educational development is the professional and institutional work through which faculty build the capability to design, teach and assess well — and in the AI era it has become a precondition for any pedagogical change to take effect. The concept spans the individual (AI literacy, confidence, competency, attitudes) and the institutional (standards, policy, quality assurance, and alignment between stated AI expectations and actual assessment design). A recurring finding across this knowledge base is that the evidence for effective practice substantially leads what most institutions have implemented, which makes development work — not more primary research — the binding constraint. The learning sciences produce the findings this work carries: where that field establishes empirically how people learn and which designs change outcomes, educational development is the institutional practice that moves such evidence into how faculty actually teach and assess. Its work, though, is bounded by an institutional edge: development builds

capability in the staff inside an institution, while the tools those staff are then asked to adopt are usually built outside it by Educational Technology Developers, whose design and procurement decisions — defaults, configurability, what survives the funding — arrive as constraints on the program rather than as products of it.

Educational development in the AI era

- **Readiness frameworks:** The EPIQ-AI framework identifies four readiness domains: epistemic, pedagogical, institutional, and quality-and-compliance. Faculty readiness is a sociotechnical alignment problem, not just an individual skills gap.
- **Check what a framework's levels describe before adopting it.** Across 16 institutionally endorsed AI competence frameworks, AI use, output evaluation and domain application were substantive in all 16, while problem formulation (7), data competence (9) and AI creation (8) were not; proficiency levels also describe learner development, occupational role or grade, so they are not directly comparable (Fitsilis (2026)).
- **Standards for technology integration:** Crompton et al. use design-based research to develop faculty standards for technology (incl. AI) integration in higher education institutions.
- **Adoption and confidence:** Teacher AI adoption research identifies concerns, support, confidence, and attitudes as key predictors. Faculty-development programs must address all four.
- **Curriculum integration:** Institutional change frameworks and assessment reform require faculty to redesign courses, not just add AI tools.
- **Training programs:** AI upskilling frameworks and TPACK-based preservice training provide models for structured faculty AI education.
- **AI-mediated professional reflection.** The Reflective Triangle Model positions AI as a cognitive mediator across self-reflection, collaborative reflection, and community reflection in a professional learning community, tested in a four-week feasibility case with six teachers; the boundary it draws is that individual insight does not automatically become shared professional knowledge (Nguyen (2026)).
- **AI Governance and policy:** Institutional AI policy analysis documents the gap between institutional ambitions and faculty support capacity.
- **AI literacy is institutionally invisible.** A systematic review of 32 studies of language-teacher AI literacy found it absent from workload models, promotion policies and resource allocation, with development fragmented and accountability displaced across institutions and agencies — so literacy development defaults to individual effort rather than structural support (Deng, Çelik & Duran, 2026).

Metaphors and shared language in educational development

Faculty hold heterogeneous, often deeply ambivalent mental models of AI, and effective development must surface and work with them. Gerhardt et al. show that engineering instructors frame AI through metaphors that both construct and constrain understanding (AI as a human-like "assistant" vs. a "tool" or "search

engine”); because instructors within the same department often hold fundamentally different conceptualizations, a shared, accurate language about GAI is a prerequisite for effective faculty development and productive departmental adoption discussions.

A practical method for surfacing these mental models is the **metaphor-analysis workshop**. Vallis, Wilson & Casey (2025) designed and validated a low-tech, collaborative workshop for faculty, staff, and students to articulate their metaphors for generative AI. Participant metaphors clustered into four categories — *Functions* (tool-like: “Swiss army knife”), *Roles* (human-like: “helper,” “frenemy”), *Qualities* (unknowable: “black box,” “slippery slope”), and *Agency* (threatening: “competitor,” “sinister robot”) — surfacing persistent tensions between human vs. machine Learner Agency and the known vs. the unknowable. The workshop helped participants surface assumptions, connect across roles, feel “not alone,” and think about the Ethics of GenAI, without requiring technical expertise. As a development tool, it gives program designers a low-barrier way to surface a team’s assumptions *before* redesigning Assessment or rolling out policy, and to address fears head-on — including the fear that AI will replace teaching roles.(Fear and awe: Making sense of generative AI through metaphor)

GenAI as identity work, not just upskilling

A threshold-informed view reframes GenAI integration as an **ontological transformation** for faculty, not a skills gap. Applying threshold concept theory (Meyer & Land), Laidlaw argues that GenAI exhibits all five threshold characteristics — *transformative* (reconstructs assumptions about assessment, pedagogy, and professional role), *troublesome* (violates beliefs about originality, human agency, and effort–achievement), *irreversible*, *integrative* (connects technology, pedagogy, epistemology, and identity), and *bounded* (GenAI fluency becomes a new marker of professional currency).(When faculty ask, "what’s the point of teaching?": GenAI as identity crisis, not skills gap)

On this account, faculty asking “what’s the point of teaching in a GenAI world?” are not deficient in competence; they are in a **liminal threshold-crossing phase** where anxiety, resistance, and confusion are necessary parts of transformation, not obstacles to eliminate. Skills-based training that answers a competence question faculty are not asking can become peripheral to the real transformation, and well-intended governance can lapse into an “enforcement illusion” — communicating rules rather than supporting change. (When faculty ask, "what’s the point of teaching?": GenAI as identity crisis, not skills gap)

Design implication: complement (don’t replace) skill building with **identity-supporting practices** — open sessions with identity questions rather than technical demos, run ongoing discipline-specific cohorts where faculty explore what GenAI means for their field’s purpose, create peer-mentoring structures that honor different transformation timelines, and distinguish fear-based hesitation (which benefits from support) from principled non-adoption grounded in legitimate disciplinary values (which deserves respect).(When faculty ask, "what’s the point of teaching?": GenAI as identity crisis, not skills gap) The metaphor-workshop model above is one concrete instantiation of this: rather than starting from technical upskilling, it opens with the interpretive, identity-laden question of what GenAI means to participants.

Empirical support for the identity-work framing. Farazouli et al. (2026) provide direct qualitative evidence for this account: 24 Swedish university teachers described GAI’s emergence as alarming and overwhelming, reporting a “state of vulnerability” (low confidence, insecurity, fear of “not being ahead of students”) and feeling “stuck” between utopian and dystopian discourses. Their limited knowledge and

experience, alongside feelings of vulnerability, highlight teachers' lack of readiness to navigate, assess, and adopt GAI — and the authors argue institutions must provide **designated spaces and time** for teachers to experiment with GAI, exchange ideas, and collaboratively develop practices and guidelines at institutional, departmental, and course levels. This grounds the identity-work and support-oriented approach in teachers' own reported experience rather than only in theory.

A programme that worked the identity question directly. Chick, Morello & Staffey (2026) report a six-week summer institute that took ten faculty from Education, Health Sciences, Business and other programs out of low AI fluency (mean self-rating 1.89 on a six-point scale) to 60% reporting high confidence in guiding student AI use and 90% positive perceptions, and they attribute the shift less to tool training than to structured, safe experimentation that opened with the existential question of professional value rather than with demos. The vocabulary change is the marker they lean on: early framings of AI as a "cheating machine" or a "dehumanizing force" gave way to "curious assistant," and their four themes — fear to curiosity, a desire for ethical clarity the policy vacuum did not supply, inclusive design as an equity amplifier, and faculty moving from gatekeepers to guides — describe a partial, deliberate reorientation of instructional identity. The ten capstone redesigns are the harder evidence, with eight of ten positioning AI as a scaffold supporting rather than replacing thinking, and the authors' **symbiotic pedagogy** formalises what participants built: complementary design, transparent process, critical integration, embedded ethical reasoning and iterative refinement. The caveat is structural rather than individual: the same participants named contradictory policy signals, personal tool subscriptions and no time release for the redesigns, so the authors conclude that resistance was never the problem and that piecemeal responses leaving policy and infrastructure untouched will fail even an enthusiastic cohort.

Development as mediation, and the first question a developer asks. Sithole (2026) studies academic development — the field's older name, and the term used by the *International Journal for Academic Development*, which published the paper — at two South African Historically Disadvantaged Institutions, and reframes developers not as technical implementers but as **digital mediators** working across three registers: pedagogical (translating AI discourse into viable teaching, learning and Assessment practice), ethical (holding automation against Academic Integrity, innovation against care), and institutional (working the liminal space between management imperatives and academic concerns). Two findings matter for program design. First, the filtering question is contextual before it is technical — "what does this mean for teaching here, for our students from poor schools?" — and slowing adoption down counts as part of the work rather than resistance to it. Second, the affective cost is structural, not personal: developers were expected to project expertise in tools whose implications they were still working out ("I feel like an impostor. I am learning AI as I go, but the institution expects expertise"), and their response was peer professional learning aimed at judgment rather than skill, including deliberately trying to break the tools. The paper's analytical contribution is to separate digital inequality, a distributive problem, from **algorithmic coloniality**, an epistemic one that survives full access — and to place both inside Global South higher education, where development work is expected to be transformative rather than a neutral support service.

Guilt and moral discomfort as a developmental signal. Vassallo (2026) supplies the affective counterpart to the identity account. In a survey of academic staff at a Maltese university (109 responses, a 3.5% rate the paper reads as itself informative about the state of ethical debate), guilt tracked concealment rather than disclosure — limiting AI use because of unease correlated with the AI Guilt Index at r = .62 and avoiding disclosure to colleagues at r = .50 — while formal disclosure in academic outputs showed no relationship (r

= .08). Only 31.2% saw clear institutional guidelines, and the correlation between that clarity and lower guilt was weak (r = −.25, p = .010), which the paper reads as evidence that top-down mandates cannot resolve a partly emotional and identity-based problem. Its recommendations are directly developmental: treat guilt and identity concern as normal transitional responses rather than faults to correct, use structured low-stakes experimentation to move staff through anticipatory anxiety, and lean on mentorship by senior academics, since guilt was highest among early-career staff (M = 2.71) and lowest among senior ones (M = 2.03).

Practical guidance for program designers

For faculty developers, academic leaders, and instructional designers planning AI professional development, the knowledge base's evidence suggests:

Address the four adoption drivers, not just knowledge. Confidence, attitudes, support, and concerns predict whether faculty actually adopt AI — a knowledge-only workshop that ignores these is unlikely to change practice. Design development to build confidence through hands-on use, provide ongoing support (not one-shot training), and actively surface and respond to faculty concerns.(AI adoption among teachers: Insights on concerns, support, confidence, and attitudes)

Confidence and literacy are not interchangeable targets: in a 502-respondent SEM of university faculty, AI literacy was the dominant predictor of AI Well-Being (β = 0.713) while technological self-efficacy contributed little (β = 0.082), and support reached well-being only indirectly (Liu et al. (2026)).

Treat guideline demand and guideline adequacy as separate problems. Faculty at one university strongly backed institutional measures against unethical AI use (M = 4.59) while rating existing guidelines lowest (M = 2.99), and named data privacy and cultural inclusivity their weakest knowledge - a concrete target for professional development (Bilgic & Sever, 2026).

Treat readiness as a sociotechnical alignment problem. The EPIQ-AI framework shows faculty readiness spans epistemic, pedagogical, institutional, and quality-and-compliance domains. Programs that only train the individual miss the institutional levers (policy, workload, incentives, quality standards) that enable or block change — align those alongside training.(Faculty Readiness for AI-Supported Teaching and Scalable Online Program Delivery in Higher Education: The EPIQ-AI Framework for Epistemic Integrity)

Do not equate infrastructure investment with transformation. Across 125 studies, institutional investment in GenAI infrastructure and educational development correlated only weakly with actual pedagogical change (r = 0.12), while 60–70% of instructors felt unprepared to integrate GenAI — making development, not procurement, the binding constraint.(Rathnayake (2026)) **Name the failure mode, not only the effect size.** Fajardo-Ramos, Chiappe and Martínez-Pérez (2026) call it simulated innovation: tool presence signals progress, teaching and assessment formats stay intact, adoption rates and dashboards stand in for learning, and the technology release cycle sets the direction. Their diagnostic asks a development program to justify each tool against a named learning problem before adoption.

Build toward curriculum redesign, not tool adoption. The goal is faculty redesigning courses and assessment, not just adding AI tools. Ground professional development in course-level redesign work and assessment reform, and give faculty structured frameworks for doing so (e.g. assessment scales, institutional change frameworks).(A framework for institutional change in the age of AI)('A bit of chaos and madness': The AI Assessment Scale and the work of assessment reform)

Convene the village, not the individual. Across 12 academics and 17 students interviewed, GenAI-era assessment redesign exceeded any single academic's capability — inflexible processes, long lead times and workload burden were named — so the authors propose a program-wide team combining assessment-design, GenAI, subject-matter, program and industry expertise (Nicola-Richmond et al., 2025).

Run the series on the room's own data rather than imported best practice. Perl-Nussbaum and Finkelstein (2026) document a worked model from a large public R1 physics department: six biweekly sessions of 60 to 75 minutes, nineteen faculty participating across the series and about ten at any meeting, in which every session opened with local data or department-sourced materials, moved to small-group testing of AI against real anonymized student homework, and closed in collective discussion. What faculty found by testing was more useful than any package the facilitators could have imported — AI solved every problem they tried, but its feedback on real student work was uneven, prompt-dependent and surface-focused unless given explicit goals and rubrics, and students prompted shallowly and modified output superficially unless productive use was modeled. The first concrete output was a living repository of five entries — syllabus policy statements, classroom discussion materials, the student survey, AI-integrated homework tasks and assessment structures — which is why the authors treat the session structure itself as the argument rather than any content it delivered.

Anchor in a competency framework. Development should also build **pedagogical prompt literacy** — the capacity to encode pedagogical intentions into prompts — since Talebzadeh (2026) finds it is pedagogical expertise, not AI fluency, that determines the quality of teachers' AI-assisted design work.(AI-accelerated End-to-End Framework for Rapid Professional Upskilling)(AI literacy-related domains and AI-TPACK readiness among preservice mathematics teachers: A factor-informed structural equation modelling study) (The Architecture of Roles in AI-Designed Group Activities: A comparative inductive analysis of novice and experienced teachers' differentiated instruction within the IAT framework)

Sequence understanding before automation. A critical discourse analysis of 14 pieces of gray literature published between November 2022 and April 2025 advising practitioners on generative AI for constructive alignment finds that capability must precede tool access: because quality of engagement precedes quality of understanding in a Constructivism framework, risk scales inversely with familiarity, and novices are the most exposed to plausibility-driven acceptance of plausible-looking but pedagogically thin outputs. McInnes et al. (2026) further argue that development units should resist a technicist brief — helping faculty "acquire fluency" in tools that do "the heavy lifting" of course design — because that framing shuts developers out of a closed educator–GenAI loop and recasts values-led, relational development as a mediating mechanism for software adoption. The defensible alternative keeps educational developers as curators and rule-setters of any institutionally bounded retrieval-augmented alignment assistant that poses probing questions, flags under- and over-assessment and generates alternatives but never finished artifacts, with escalation to human judgment on accreditation and cross-program matters treated as a feature rather than an exception.

Surface and address fears and mental models. Before redesigning teaching, use a metaphor-analysis workshop (Vallis, Wilson & Casey 2025) to surface a team's assumptions and anxieties about GenAI — including the fear that it will replace teaching roles — and build development that responds to them rather than ignoring them.(Fear and awe: Making sense of generative AI through metaphor)

Model AI literacy and measure real gains. Faculty development should itself embody the practices being taught — using AI pedagogically, evaluating outputs critically — and should assess demonstrated

competence rather than self-reported confidence, since self-perception reliably overestimates AI skill.(How to Assess AI Literacy: Misalignment Between Self-Reported and Objective-Based Measures)(Efficacy of an Intensive Generative AI Professional Development Program on Pedagogical Content Knowledge (AI-PCK) and the Comparative Analysis of Learning Gain between Experienced and Pre-service Teachers)

Do not assume subject-matter expertise carries over to GenAI. Sutedjo, Chowdhury & Liu (2026) surveyed 127 U.S. research-university faculty using the TPACK-21 instrument and found content knowledge (CK) showed **no significant correlation** with technological knowledge or any technology-integrated domain (r =.11–.15, ns) — disciplinary expertise did not predict GenAI-integration knowledge. The technology-integrated domains (TPK, TCK, TPACK) inter-correlated so strongly (r =.81–.91) that they may function as a single GenAI-integration factor. Practically: build GenAI integration through **discipline-specific** activities that connect GenAI affordances to each faculty member's subject matter, and treat the technology-integrated domains as one shared GenAI-literacy foundation rather than train them as separate skills.(Assessing faculty self-perceived knowledge in using generative AI to teach 21st-century skills)

Discipline-specific smart-classroom models. Zhu, Liang, Mao, and Wang (2026) show how a mathematics M.Ed. course can be enhanced with intelligent educational technologies (automated scoring, personalized recommendations, multi-AI feedback) integrated across pre-, in-, and post-class stages within a three-dimensional smart-classroom framework. Their quasi-experiment found statistically significant gains in instructional-objective design proficiency, offering a transferable **D-T-E Model** (Disciplinary Demand–Technological Empowerment–Evaluation Loop) for teacher educators and educational developers looking to move smart-education frameworks from macro concepts into discipline-specific practice.

Measure attendance, not the feeling of engagement. In a six-month Intelligent-TPACK program for 64 university teachers, attendance rate predicted the gain in AI competency ($\beta = .407$, $p = .001$) while self-perceived participation did not ($\beta = .049$, $p = .692$), which the authors read as concrete behavioral investment against surface-level engagement (Tan, Cheng & Ling, 2025). The program paired online lectures with three face-to-face workshops, then required teachers to revise their instructional designs and implement them the following semester, and the authors recommend tying attendance into appraisal alongside meaningful incentives.

Benchmark against what faculty themselves report. Watson & Rainie (2026)'s survey of 1,057 US faculty finds the institutional layer thin in ways program designers can measure directly: 59% judged their school unprepared to use generative AI effectively for preparing students for the future and 68% said it had not prepared faculty to use it for teaching and mentoring, while the structural response ran to a task force in 55% of institutions but an AI literacy general education outcome in only 13%. Faculty had not waited for policy — 87% wrote their own assignment-level rules against 48% who could point to an institutional one — and they named colleagues' resistance (82%) and unfamiliarity (83%), not mandate, as the obstacles to departmental adoption. For development programs this argues for treating peer norms, shared assignment-level policy language and explicit measures of institutional readiness as part of the intervention rather than leaving them to the policy document.

Instructor response reflects power centers, not attitude. In an instrumental case study of 33 writing instructors, four polycentric power centers — the global GenAI trend, the university/department, colleagues,

and students — shaped practice, and adjuncts constrained by limited discourse power shifted from detection toward teaching acceptable use (Zuo et al. (2026)).

- **Six professional-development families, three well evidenced, and a clear winner.** A review of 78 studies of AI-supported instructional design sorts documented PD into compact embedded modules (2-4 weeks), semester-long microlearning, task-based design cycles, collaborative dialogue-based question chains, critical co-discovery, and self-directed practitioner learning. Outcome evidence is strongest for **compact embedded modules**: a three-week module produced statistically significant gains across all six Intelligent-TPACK domains with medium-to-large effect sizes, and a four-week program with **436 pre-service teachers and a control condition** is the strongest controlled evaluation in the corpus (Spyropoulou & Kameas, 2026).
- **Three design features separate the best-evidenced interventions.** Ethics embedded as **distributed practice with checkpoints at every task** rather than a stand-alone session; **performance-based competence assessment** using lesson plans, decision logs and micro-teaching, motivated directly by the unreliability of self-report; and prompt engineering developed as reflective, pedagogically grounded practice. Adoption is not the same lever as performance: across 200 teachers in North Sumatra, AI use had no direct effect on teacher performance ($\beta = 0.112$, $p = .087$) while organizational citizenship behavior carried it indirectly, so faculty-development work aimed at collaborative, extra-role use is the version the evidence supports (Sherly et al. (2027)). A companion two-week study found rapid gains in knowledge and confidence while identifying bias detection as the weakest emerging competence — a gap that persisted into the longer module, consistent with ethical perceptual capacity developing more slowly than technological familiarity.

Common Misconceptions

“A skills workshop is the intervention educational development needs.” Readiness is a sociotechnical alignment problem, not an individual deficit, which is why a standalone “AI workshop” falls short of the need it addresses. A program that worked the question directly was a **six-week summer institute** taking ten faculty from Education, Health Sciences, Business and other programs through identity-level work. Duration and cohort are not incidental to that design; they are what distinguishes it from a feature tour.

“Clearer institutional guidelines will resolve faculty unease.” Guidelines help and they do not reach the problem. Only **31.2%** of academic staff at a Maltese university perceived clear institutional guidelines, and the correlation between guideline clarity and lower guilt was **weak ($r = -.25$, $p = .010$)**. A weak relationship at that scale means top-down mandates cannot settle what the paper reads as a partly emotional and identity-based problem — the fifth of the variance they explain is not the fifth that matters.

“Guilt about AI use indicates rule-breaking.” It tracks concealment rather than disclosure: limiting AI use because of unease correlated with hiding it, not with prohibited behavior. Reading guilt as evidence of misconduct therefore misidentifies its source, and treating it as a compliance signal will push the behavior further out of view.

“A low survey response rate means faculty have no strong feelings.” The paper reads its **109 responses (a 3.5% rate)** as itself informative about the state of ethical debate — a low response to a question about discomfort is a finding about that discomfort, not an absence of one. And a GenAI integration framed purely

as upskilling misses the identity question some faculty are actually asking: what the point of teaching is in a GenAI world.

The field

History of AI in Education

> **History of AI in Education** — the study of how artificial intelligence and education have co-evolved since the mid-20th century, and how past conceptual, terminological, and design choices continue to shape today's debates about AI in learning. Rather than treating generative AI as a sudden, unprecedented force, a historical lens reveals recurring tensions — control vs. agency, standardization vs. Creativity, automation vs. augmentation — that have structured AI in education since its origins.

Questions to Consider

- Today's generative AI is often described as an unprecedented revolution. How might that framing ('chronocentrism') prevent us from seeing the recurring patterns beneath it?
- The field was almost named 'cybernetics' instead of 'artificial intelligence.' How might that single naming choice have shaped whether we see machines as independent intelligences or as part of interconnected feedback systems?
- The page frames AIED history as a tension between control (Anderson's cognitive tutors optimizing instruction) and agency (Papert's constructionism empowering learners). Where do your own AI-in-education choices fall on that spectrum — and why?
- Personalization, the page argues, has two meanings: varying the path to the same outcome, or enabling diverse, learner-directed outcomes. Which kind of personalization does your institution actually pursue, and which do you think it should?
- If today's GenAI debates 'mirror' these historical tensions, what past mistakes might we be repeating — and what might we avoid by remembering them?
- The page claims technical design choices embed value judgments about learning's purpose. Can you identify a design decision in an AI education tool you've used that quietly favored standardization over learner agency — or vice versa?

Introduction

The field's history is not a linear progression but a series of contingent decisions whose effects still echo. Understanding this history guards against "chronocentrism" (the bias of treating current developments as uniquely revolutionary), helps avoid repeating past mistakes, and reveals how choices about framing and terminology — not just technology — steer the trajectory of AI in education.

Key historical threads

From cybernetics to "artificial intelligence." When John McCarthy planned the 1956 Dartmouth Summer Research Project, he deliberately chose the term *artificial intelligence* over *cybernetics* — partly to distance the field from Norbert Wiener and his focus on analog feedback. This naming decision framed machine capabilities in direct comparison to human cognition (anthropomorphic framing), steering research priorities,

public perception, and ethical debate for decades. Had the field kept the cybernetic framing, the article imagines we might now speak of “cybernetic learning systems” emphasizing feedback and interconnection rather than “AI tutors” positioning the machine as an independent source of intelligence.

The cognitive revolution and the roots of ITS. Early pioneers — Herbert Simon, Allen Newell, Marvin Minsky, John Anderson — were not merely modeling cognition; they were investigating fundamental questions about learning and instruction. Their work produced information-processing models of human cognition that became foundational to educational psychology, and led to Intelligent Tutoring Systems (ITS), rooted in the heuristic-search and expert-systems paradigms of 1960s–70s AI. These systems aligned naturally with existing structures of assessment and standardization, and eventually coalesced into the AIED community.

Control vs. agency: Anderson and Papert. Two competing visions emerged, embodied in John Anderson and Seymour Papert. **Anderson’s** cognitive tutors (ACT/ACT-R theory) decomposed knowledge into production rules, provided precise individualized feedback, and reinforced traditional educational structures — a vision of AI as a tool for optimizing instruction. **Papert’s** constructionism (Logo, “microworlds,” debugging-as-learning) saw computers as environments where children construct knowledge through creative experimentation — a vision of AI as an instrument of intellectual empowerment that challenged institutional hierarchies. This “essential tension” between control and agency is the through-line of the field’s history.

Two forms of personalization. Personalization has two distinct interpretations that map onto these visions. The first maintains uniform outcomes while varying the path (rooted in Skinner’s teaching machines; the Khan Academy vision of tutoring to mastery). The second embraces diverse outcomes — learners pursuing individual interests and talents, unconstrained by standard curriculum boundaries (Zhao, 2024). The ITS model supports the former; constructionism the latter.

Lessons for the GenAI era. Today’s debates about generative AI closely mirror these historical tensions. GenAI is often positioned as a next-generation intelligent tutor (extending Anderson), raising concerns about surveillance, data collection, and standardization. Alternatively it can be a tool for creative agency (extending Papert), requiring us to rethink assessment and accept more ambiguous outcomes. As Mishra et al. conclude, institutional forces repeatedly favor approaches that reinforce existing structures — and the language and metaphors we choose will shape future possibilities. Rismanchian & Doroudi’s AI×Ed framework gives this intuition empirical grounding: locating papers from AIED proceedings (1985, 1993, 2021, 2024) and IJAIED (2004, 2014, 2021) along two axes — the role of AI (applied tool vs. analogy to human intelligence) and the end user — they trace a field that moved from a diverse mix, including substantial early research using AI as an analogy to human intelligence (computational models of learning, Papert’s microworlds, agent-based models of knowledge acquisition), toward a near-exclusive focus on applied, instrumental uses by the 2000s. Notably, the generative-AI era appears to partially reverse that trajectory: by AIED 2024, three of the four slots in the “AI-as-analogy” quadrant were LLM-built, and one of those took a best-paper award for LLM-powered teachable agents.

The recent impact of generative AI

The arrival of generative AI — a broad family that includes large language models (text), plus image, audio, and video generators — marks the most consequential inflection point in AIED history since the field’s

founding. LLMs are the most prominent member of this family and the driver of most classroom impact, but generative AI as a whole (capable of producing novel text, images, sound, and code) is the broader force reshaping education. It is best understood against AIED history rather than as a clean break. Several features make the generative-AI era distinctive:

Scale and reach. Unlike the cognitive tutors and ITS of earlier decades, which operated in controlled lab and classroom settings, LLMs reached hundreds of millions of learners and educators within months of release, entering everyday writing, homework, and instruction almost immediately. The GenAI debate moved from specialist journals to classrooms, boardrooms, and legislatures with unprecedented speed.

A new kind of capability. Earlier AIED systems modeled cognition and delivered structured instruction (the Anderson tradition). LLMs perform open-ended generation — producing essays, explanations, code, and dialogue — which foregrounds learner agency and creativity (the Papert tradition) in ways earlier ITS could not. This is why the current moment re-ignites the control-vs-agency tension so sharply: the same tool can be deployed as a next-generation intelligent tutor (controlling outcomes) or as a creative co-writer and thinking partner (amplifying agency).

A reversal of the access equation. Historically, personalized tutoring was scarce and expensive; GenAI made adaptive one-on-one support nearly free and universal — dramatically lowering the accessibility and cost barriers that shaped earlier AIED. But it also introduced new risks: algorithmic bias, hallucination, surveillance, data collection, and the de-skilling of educators.

Renewed concern about AI literacy and misuse. The generative-AI era made AI Literacy urgent and reframed Academic Integrity debates (detection vs. dialog), while reviving long-standing concerns about automation, standardization, and epistemic dependence. These are the modern expressions of the field's original tensions.

Chronocentrism's risk. As Mishra et al. warn, the hype around generative AI often lacks historical awareness, letting tech evangelists dominate the conversation. Understanding that today's GenAI debates echo the Anderson–Papert divide and the 1955 cybernetics naming decision helps us make deliberate choices rather than treating the present as inevitable. The real question is not what generative-AI tools can do, but what we want them to do — a decision shaped by where we have been.

Implications

- **Read hype historically.** Recognize that each new AI wave is framed as revolutionary; historical awareness reveals continuity and helps resist corporate dominance of the conversation.
- **See design choices as value choices.** Technical decisions about AI in education embed ideological positions about learning's purpose — surface and interrogate them.
- **Weigh control against agency deliberately.** Whether AI should optimize toward standard outcomes or enable diverse, learner-directed outcomes is a genuine choice with institutional and political consequences, not a technical given.
- **Preserve learner agency.** The recurring resistance to standardization and control in favor of open-ended, learner-centered approaches is a durable thread worth defending.

Common Misconceptions

“AI in education began with ChatGPT.” It did not, and the belief is costly because it makes every earlier lesson invisible. Intelligent tutoring descends from the heuristic-search and expert-systems work of the 1960s and 70s, and the AIED community formed around it decades before large language models. Mishra et al. show the current debates reproducing a divide already explicit in Anderson’s cognitive tutors and Papert’s constructionism, so a reader who dates the field to 2022 will re-derive arguments the field settled, abandoned, or lost once before.

“The field has steadily abandoned AI-as-analogy in favor of applied tools, and generative AI continues that trend.” This is the most instructive correction on the page, because the trajectory is real but not monotonic. Rismanchian and Doroudi’s positional analysis of AIED 1985, 1993, 2021 and 2024 and IJAIED 2004, 2014 and 2021 does show a drift from a mixed field toward near-exclusive applied instrumentality by the 2000s. But at AIED 2024, three of the four papers in the AI-as-analogy quadrant were LLM-based, including best-paper work on LLM-based teachable agents. Generative AI partly **reverses** the trend rather than extending it, which is why treating it as “the next intelligent tutor” misreads where the research frontier actually moved.

“Personalization means adapting the difficulty to each learner.” That is only one of two incompatible senses, and conflating them hides a political choice. In the first sense the outcome is held fixed and only the path varies, the lineage running from Skinner’s teaching machines through mastery-based tutoring. In the second the outcomes themselves diversify, as learners pursue individual interests unconstrained by standard curriculum (Zhao, 2024). An ITS implements the first; constructionism the second. A tool described as “personalized” has told you nothing until you know which it means.

“‘Artificial intelligence’ was simply the obvious name for the field.” The term was a deliberate choice. When McCarthy planned the 1956 Dartmouth project he favored *artificial intelligence* over *cybernetics* partly to distance the work from Wiener’s analog feedback tradition. That single decision framed machines in direct comparison to human cognition, and the anthropomorphic framing it installed still shapes research priorities, product language, and the ethical questions the public asks.

Putting It into Practice

For instructors and instructional designers

- Name the tradition your tool belongs to before adopting it. Ask whether it optimizes toward fixed outcomes or opens learner direction, because that answer, not the feature list, determines what it will do to your assessment design.
- Interrogate the word “personalized” in every vendor claim, and get an answer in terms of the two senses above. A product that varies pacing toward a common standard and one that lets students diverge are not substitutes.
- When students present GenAI as unprecedented, the history is teachable content in its own right. The Anderson-Papert framing gives them a vocabulary for arguing about AI rather than only using it.

For developers

- Interface language is a design decision with a lineage. Calling your system an “AI tutor” inherits Anderson’s framing and the expectation of optimizing toward standard outcomes; calling it a “microworld” or “learning environment” inherits Papert’s. Neither is neutral, so choose deliberately.
- If you are building in the analogy tradition (models of learning, teachable agents, simulations of knowledge acquisition), say so. That quadrant was nearly empty for two decades and is repopulating; the positioning is a differentiator and the evaluation criteria are different.

For researchers

- Use the historical corpora as a baseline rather than treating the present as the only available comparison. The AIED proceedings for 1985, 1993, 2021 and 2024 and IJAIED for 2004, 2014 and 2021 are a ready-made longitudinal sample of the field’s own claims.
- Cite lineage when you claim novelty. A claim that a system “personalizes learning” or “models the learner” is only novel relative to a specific prior tradition, and the tradition is documented.

Interpreting and Applying AIEd Research

> **Interpreting and applying AIEd research** — how to decide whether an AI-in-education finding is worth acting on, whether you teach, run a program, design a course, or build software. You do not need statistics to use this page. It starts with the question a practitioner actually has — *should I do this?* — works through the few things that answer it, and keeps the technical detail in a later section for anyone who wants or needs it. The short version: a finding is worth acting on when you know what was compared, what was measured, who was studied, and whether the tool still exists in the form that was studied. Most claims that reach instructors, administrators and developers fail one of those four.

Questions to Consider

- A vendor, a news story, or a colleague says an AI tool improved learning. What is the one thing you would want to see before trying it in your own course — and would you know where to look for it?
- Every article page in this knowledge base now has a **What this means for practice** section, and most have a **Limitations** section. Reading the two together, what does each tell you that the other does not?
- Students practice with an AI tool and do better on the practice work, then do worse on the closed-book exam. Which number is the learning outcome your course cares about — and would your current assessments catch the difference?
- A study promises a big improvement, but it followed 30 students in one course at one institution, and the version of the tool studied is no longer the version anyone uses. Which of those two facts worries you more, and why?
- Many AI tools increase how much students use them without increasing how much they learn. If you had to choose between a tool that raises engagement and one that raises unassisted performance, what evidence would settle it?
- You are asked to approve or buy a tool on the strength of the vendor's own effectiveness numbers. What would you want disclosed about how those numbers were produced?

Introduction

This page is for people who have to decide something: an instructor wondering whether to change an assignment, an Administrators weighing a pilot, a learning designer building a course, a software developer deciding what a feature should do, or a researcher explaining a finding to any of them.

Two habits make the difference, and neither needs research training.

Read the two sections written for you first. Every article page here now carries a **What this means for practice** section — usually three to five concrete actions derived from that study — and most carry a **Limitations** section stating what the study cannot support. Read those before the study's findings, not after.

The practice section tells you what the study is good for; the limitations section tells you where it stops. If the practice section is missing or vague, treat that page as unfinished rather than as evidence.

Judge the claim, not the confidence of the claim. Claims about AI in education are usually accurate about *something* and misleading about the thing you care about, because a study and your classroom differ in four ways: what it was compared against, what it measured, who took part, and which version of the tool was used. The rest of this page gives you the checks in plain language, then the evidence behind each of them for readers who want it.

What follows is also not a replacement for its neighbours. Research Methods in AI in Education covers how designs are built, Limitations in AIEd Research catalogues the literature's recurring weaknesses, AIED Evaluation covers how systems and outputs are evaluated, and Differential Effects Across Learner Groups covers who a finding does and does not include.

Four questions that settle most claims

Ask these before you spend time, money, or a semester on something.

1. What was it compared against, and was that comparison fair? "Students who used the AI did better than students who didn't" only tells you something if the other students were doing something real. If the comparison was business as usual — or nothing — then the finding bundles the tool together with extra time, extra attention and novelty. What to look for: a **control group** that got a credible alternative, and random assignment to the two conditions.

2. What exactly did they measure? This is where most exciting claims quietly fail. Test scores, homework quality, Motivation, attitudes and engagement get pooled into a single "achievement" number, or a measure of performance *with the tool present* gets reported as learning. Learning that depends on the tool being there is not the same as learning that lasts. What to look for: what the instrument measured, whether it was validated for that population, and whether an outcome was measured **without** the AI in the room.

3. Who was studied, how many, and for how long? Thirty students in one course is a signal, not a result. A four-week intervention cannot tell you about a year. And a study of students unlike yours is still useful — it is a hypothesis about your setting, not a prediction. What to look for: sample size, how participants were recruited, single site, duration, and whether any subgroup was large enough to analyze.

4. Is the tool still the tool that was studied? AI capability moves faster than publication. A 2025 finding describes the 2025 model generation — sometimes a specific version, sometimes a configuration nobody uses now. That does not make the finding false; it makes it dated, and it means the claim should be re-checked rather than inherited. What to look for: model version and the data-collection window.

What the evidence says about AI claims in general

If you remember one thing from this page, remember that the headline number is usually inflated and the comparison is usually weak. That is not a fringe view — it is what audits of the field itself report. Several well-designed studies do show real gains; the point is that the burden of proof sits with the claim.

- **About two-thirds of the average effect disappears** once you correct for the fact that impressive results get published and unimpressive ones do not. Bartoš et al. (2026) pooled 1,840 effect sizes

from 67 reviews and found the corrected average was roughly one-third of the published median — SMD 0.196 against 0.67.

- **A product name is not a teaching method.** Auditing the comparisons behind a prominent meta-analysis, Weidlich et al. (2025) found only **21%** had a well-defined treatment, a control group and a valid learning measure — and the reported advantage for "using ChatGPT" came out larger than for purpose-built intelligent tutoring systems (g = 0.7 against 0.66), which is a warning sign rather than a triumph.
- **Performance with the tool is routinely mistaken for learning.** In one K-12 math study, students practicing with a general-purpose chatbot earned better practice grades and then scored **about 17% worse** than peers with no AI access on the closed-book final (Stanford's evidence base for AI in K-12).
- **The field's own reviews do not survive audit.** O'Neill's (2026) audit of **14 peer-reviewed meta-analyses** claiming AI improves education found that **none** provided a valid basis for the claims it advanced, and among 46 randomly selected primary studies, **61%** presented validity concerns. The problem is not one bad paper; it is a reporting culture.
- **A review can quantify the reporting skew in its own corpus.** A systematic review of 155 higher-education studies found 117 (75.5%) reported successful implementation, 124 (80.0%) covered short-term impact only, and just 23 (14.8%) reported on Ethics, equity or governance failures — the imbalance the checks above describe, measured on the review's own evidence base (Nyamboga (2026)).
- **Self-reports flatter everyone.** People rate their own AI skills about **40%** higher than performance measures show, which is why satisfaction and confidence surveys are the weakest evidence you can act on (Self-Report Measures, Educational Measurement).
- **Most products already in classrooms have no independent evidence at all.** Instruction Partners' 2025–26 learning tour profiled 20 student-facing AI products and found that, of the 16 with complete profiles, only seven had an independent review examining student achievement across student groups in the US; two were studied only abroad, four had studies underway and three relied on internal data alone. The authors argue that independent causal studies covering priority groups should be the expectation for all student-facing products — not yet the norm for tools schools are already using.

Turning a finding into a decision

The sequence that saves the most wasted effort, in order.

1. **Write down your outcome first.** Not "use AI more" but "students can do X without the tool". If your outcome is unassisted performance, then a study that measured assisted performance is adjacent evidence, not direct evidence.
2. **Find the comparison and the measure** — in the study, or in the practice section of its article page. If either is missing, treat the claim as a demo rather than a finding.
3. **Read the limitations section as instructions, not disclaimers.** "Single course, self-reported outcomes, four weeks" tells you exactly which of your assumptions the study does not cover.

4. **Check the version and the date.** If the study used a model generation two years old, plan to re-test rather than assume.
5. **Name the enabling conditions.** Cost, licenses, staff time, data rules, and whether students must pay for the tier that actually works. Studies rarely carry these, and they decide whether an intervention survives a semester. In a faculty-development study of ten participants, everyone said they would keep using AI, while the same people described personal subscriptions for tool access and no time support for the redesigns they had planned.
6. **Pilot small, and measure the unsupported condition.** A short pre/post with one assessment done without the tool beats a satisfaction survey. Small and honest beats big and rhetorical. See Learning Design for where this fits in course design.
7. **Diary a review date, and be willing to drop the claim.** When a study's premise is a capability that no longer exists, the honest move is retiring the claim rather than citing it indefinitely — the same discipline this knowledge base applies to its own pages.

Words you will meet in the research

Plain translations, so you can skim a study or a vendor page without a methods background.

- **Effect size** — how big the difference was, on a scale where 0 is nothing. Treat small values as "a nudge", not "a transformation".
- **Statistically significant** — unlikely to be pure chance *in this sample*. It says nothing about whether the effect is large, or whether it will happen in your class.
- **Confidence interval** — the range of results the data cannot rule out. If the range includes zero, the finding may be nothing at all, however interesting the headline.
- **Meta-analysis** — a study that pools many studies. Powerful, and only as good as what it pooled, which is why reviews get audited.
- **Publication bias** — interesting results get published and boring ones do not, so the literature's average looks rosier than reality.
- **Self-report** — people describing themselves. Useful for attitudes, weak for competence or behavior.
- **Control group** — the comparison condition. The single most important thing to look for.
- **Pre/post** — measured before and after with no comparison group. Suggestive, never conclusive.
- **Subgroup analysis** — results for a slice of the sample. Usually underpowered, so treat it as a hypothesis.
- **Replication** — someone else got the same result. Rare, and the strongest evidence available.
- **Benchmark** — a fixed task set for scoring systems. Scores move when the target moves, so check the date.

When to slow down anyway

- **The claim comes from the vendor, on the vendor's metrics.** That can still be informative — one AI tutoring provider reports an engagement metric calibrated against human experts at F1 0.83, with improvements coming from over 40 experiments in five months (Udeshi et al., 2026) — but

the construct, the raters and the metric are the vendor's choices. Ask for the comparison group and the unassisted outcome.

- **Automated scoring is treated as solved.** High agreement with human raters is reliability, not quality. In one scoring study, human raters agreed with the multi-rater consensus at about r = 0.88, so automated scores near r = 0.85 were already at the task's own measurement ceiling (Know When to Trust AI Scoring).
- **The reference list is doing heavy lifting.** Thirty reference entries containing verifiably fabricated bibliographic information were confirmed across 14 computing-education papers, all from 2025 and 2026 (Denny et al., 2026). If a claim rests on a citation, check the citation.
- **Nobody measured the behavior your policy depends on.** Across 493 deduplicated records and 14 priority studies, no study measured whether verification succeeded *and* what the learner then did with it, judged against an independent standard of output quality (verification and reliance calibration). Course policies depend on exactly that behavior.

If you are building or buying a tool

The same checks invert into design requirements, and the knowledge base's evaluation pages carry the detail (AIED Evaluation, Automated Assessment).

- **Make the comparison part of the feature spec.** Decide what a learner would otherwise be doing, and be able to say why your tool beats that — not why it beats nothing.
- **Measure the unsupported condition.** If your outcome is learning, include a task completed without the tool; assisted performance alone will mislead you as much as it misleads your buyers.
- **Report how your automated judgments were validated** — the gold standard, the calibration target, who adjudicated disagreements — and report it as reliability rather than quality.
- **Name the version and the date** in any effectiveness claim, because your next release invalidates it.
- **Show the counterweights:** cost per student, Accessibility, data handling, and what happens to learners on the free tier. See AI Use Disclosure, Privacy and AI Governance.

For readers who want the evidence

The checks above are not folk wisdom; they come from documented failures in this literature. This section keeps the detail for anyone reviewing a paper, defending a decision, or arguing that a tool should be evaluated properly.

The validity failures have a distribution, not just a presence. In O'Neill's (2026) 46 audited studies, dependent-variable mismatch was the most common problem (n = 15) — the measure did not capture what the claim asserted — followed by independent-variable mismatch (n = 11), experimental design problems (n = 7), data extraction problems (n = 6), absence of a control group (n = 6) and nonrandom group assignment (n = 6). Of the 14 meta-analyses, twelve treated multiple effect sizes drawn from the same primary study as independent, which inflates the apparent evidence base.

Subgroup claims are usually undecidable in the studies that make them. The GCSE science micro-RCT reports a treatment-by-status interaction of **0.57 marks (95% CI -2.25 to 3.39)**, with stratified estimates of **g**

= 0.28 (95% CI -0.04 to 0.59) for one group and **g = 0.35 (95% CI 0.18 to 0.52)** for the other. An interval crossing zero is not an equity finding; it is a question for a local pilot.

A synthesis can satisfy its own protocol and still pool unweighted quality. Doğan et al. (2026) state plainly that they used no formal quality appraisal tool, treating their inclusion criteria as the rigor threshold, so a quasi-experimental study and a randomized one contributed equally — and their heterogeneity reads **I^2 = 82.98% under a fixed-effect model but 15.75% under the random-effects model**, which is why a heterogeneity figure quoted without its model cannot tell you how inconsistent the corpus is.

Validation of automated judgment is part of the result. Agreement with human coders is a reliability statement, and the ceiling above shows why it is not the same as quality (machines misread pedagogical quality).

Tool vintage is a first-class limitation. A review of AI-assisted assessment notes that its own findings reflect specific model versions at specific times, and that field movement makes any account of model capabilities potentially outdated within months (AI-Assisted Assessment and Instruction in Higher Education). Scope claims to their generation: "generative AI improved X" is not portable, while "GPT-4-era tooling, in this task, with this Scaffolding" is.

Benchmark targets move, so a result that a system saturates or fails today can invert with the next release; saturation and contamination checks belong beside any benchmark-based claim.

Reading this literature alongside its own critics is normal practice here. The reporting-side checklists for authors and reviewers are in the FAQ on reporting and interpreting AI research, and the appraisal habits in this page pair with Theory Development in AI in Education when a claim is theoretical rather than empirical.

A short checklist

1. State your outcome in one sentence, including whether the tool is present in it.
2. Find the comparison. No credible comparison, no decision.
3. Match the measure to your claim, and prefer an unassisted outcome.
4. Deflate the number: read the bias-corrected effect, not the headline.
5. Check the model version and the study's dates.
6. Read the limitations section as instructions for what you still do not know.
7. Cost it: licenses, tiers, staff time, data rules.
8. Pilot small with an unassisted measure, then decide.
9. Diary a review date a year out, and be ready to retire the claim.

Common Misconceptions

"A published meta-analysis is settled evidence about AI in education." The field's syntheses have not survived audit. O'Neill's (2026) audit of **14 peer-reviewed meta-analyses** claiming AI improves education found that **none** provided a valid basis for that conclusion. A pooled effect size is only as good as the studies pooled, and in this literature the pooling has routinely included designs that could not attribute the outcome to AI. Before you quote a meta-analytic number, ask what it aggregated.

“The bigger effect size belongs to the better intervention.” Often the opposite. In the review context this page documents, only **21%** of studies had a well-defined treatment, a control group and a valid learning measure — and the reported advantage for “using ChatGPT” came out *larger* than for purpose-built intelligent tutoring systems. Weakly specified treatments tend to produce inflated effects, because the comparison is vaguer and the outcome measure looser. A larger number is a reason to look at the design, not a reason to prefer the intervention.

“Higher grades while using the tool indicate the tool taught more.” In one K-12 math study, students practicing with a general-purpose chatbot earned better practice grades and then scored **about 17% worse** on unassisted assessment. Practice performance measured with the tool present is the inflated measure; the unassisted one is the outcome, and only one of them was rising.

“If the effect is real, the implementation details do not matter much.” They are the effect. A study that followed 30 students in one course at one institution, on a version of the tool nobody now uses, has produced a finding about a configuration that no longer exists. Treatment specification, version, and setting are part of the claim rather than context around it.

Limitations in AIEd Research

> **Limitations in AIEd research** — the recurring weaknesses and constraints that affect how much confidence we can place in AI-in-education findings, and how readers should interpret them. These cut across individual studies: methodological limitations (generalizability, sample size, validity, self-report), the speed problem (AI and findings date quickly while publication lags), research-practice limitations (reproducibility, FAIR practices, proprietary tools), and weak theory use. Methodological limits are measurable rather than impressionistic: in a critical review of 80 HCI studies of critical thinking with AI, 42 (52%) ran no control group and most of the rest relied on self-report, so the field's positive findings rest on designs that cannot separate AI's effect from ordinary reflection (A Critical Review of Critical Thinking in HCI Research About AI). Outcome coding is uneven in the same way: a systematic review of 103 higher-education studies sorted its corpus into a four-level outcome typology and placed 56% of it in a single conditional pattern, where confidence and motivation rose without a matching gain in durable competence (Generative AI in higher education: A systematic review of empirical uses, outcomes, and risks).. Recognizing these limits is essential for reading the literature critically and for designing stronger studies.

Questions to Consider

- How much would you trust a headline like 'AI tutoring boosts learning by 30%' if you learned it came from 30 students in one course at one institution? The page flags generalizability and small samples as recurring limits — what would you want to know before acting on any single finding?
- A striking limitation is the 'speed problem': AI evolves faster than findings get published, so a study of one model generation may already describe an obsolete system. How should this change the confidence you place in AI education research?
- Many studies rely on self-reported attitudes and usage, which are biased — people overestimate their competence and under-report misuse. Have you ever answered a survey about your own skills or behavior in a way that didn't match reality? Why do perception-based measures so often diverge from objective performance?
- The page notes that familiar frameworks like Bloom's taxonomy are often misread as strict ladders, and that even widely used theories like cognitive load theory have been challenged. When have you seen a theory invoked as settled truth in a context where its own evidence was actually contested?
- Most AI research depends on proprietary, opaque models whose data and updates you cannot inspect. If you cannot verify exactly what model produced a result, how much can you trust claims built on it — and what would make findings more reproducible?
- If you are an instructor or designer without time to read primary research, how do you decide which AI claims are trustworthy enough to change your practice — given that the literature is fragmented, provisional, and written for researchers?

Introduction

AI in education is a fast-moving, heterogeneous field, and its evidence base carries a distinctive set of limitations that researchers, practitioners, and policy-makers should weigh when using any finding. Some of these are shared with the broader Learning Sciences and psychology literature; others are amplified or made unique by the nature of AI itself. This page organizes them into four cross-cutting areas.

Methodological limitations

The knowledge base's research methods page details the strengths and limitations of each design. Several limits recur across designs and deserve particular attention:

- **Generalizability.** Findings from a single course, institution, discipline, or national context may not transfer. Small, convenience, or single-institution samples limit external validity; results from one AI tool rarely extend to a different tool or context.
- **Cross-national belief comparisons carry a measurement risk.** A five-country survey of 1,405 K-12 teachers used automated machine translation without back-translation or measurement-invariance testing and measured plagiarism and Creativity concern with single items, so its country contrasts cannot be read as equivalent constructs (Xiu et al. (2026)).
- **Synthesis-level rigor is a separate axis from primary-study rigor.** A meta-analysis can satisfy its own inclusion criteria and still pool studies that differ in design, implementation fidelity and outcome measure without weighting any of that: Doğan and colleagues (2026) state plainly that they used no formal quality appraisal tool and treated the inclusion criteria as the rigor threshold, so a quasi-experimental study and a randomized one contributed equally to the pooled STEM estimate. The same review shows a related reporting hazard: its heterogeneity is quoted as I^2 = 82.98% under a fixed-effect model and I^2 = 15.75% under the random-effects model, meaning readers who lift a single heterogeneity figure without its model cannot tell how inconsistent the corpus actually is. Appraise a synthesis on how it handled dependent effect sizes, quality, and heterogeneity, not only on whether it followed a search protocol.
- **Retrieval design sets a synthesis's headline numbers.** In a scoping review of 195 Teacher Education studies, digital competence and TPACK were explicit search descriptors while instructional design and assessment had no equivalent, so the reported 46.5% and 1.9% characterize the corpus the search returned rather than the field (Patiño Hernández et al. (2026)).
- **Small sample sizes.** Many AIED studies are underpowered — too few participants to reliably detect meaningful effects or to support the strong claims sometimes drawn from them.
- **Data augmentation can manufacture the headline metric.** In an automated essay scorer whose training partition held 83 students' work, generated level-1 responses — templates, truncation, keyword removal — lifted Focus agreement by +0.346 quadratic weighted kappa off a 0.028 baseline, so the strongest ordinal signal rested on text no student wrote (Firdausi et al. (2026)).
- **Endpoint scores can hide the thing being studied.** In a PRISMA review of 103 higher-education studies, 56% reported gains that were conditional on scaffolding or verification, and null grade differences often accompanied real changes in process — more debugging, more checking cycles

— so grades alone cannot tell whether GenAI strengthened or hollowed out practice (Hawi and Samaha (2026)).

- **Validation design can manufacture the headline number.** Nanayakkara and Halloluwa (2026) benchmark fifteen models on EEG-based familiarity and show that standard stratified cross-validation allows temporal leakage and reports up to 0.9853 F1, while trial-independent Group K-Fold validation drops the peak to 0.6038 F1 — still above chance, but far from the quoted result.
- **Benchmarks can supply the failures they report.** Expert re-grading of 250 rejected physics items attributed 238 (95.20%) to benchmark or grader errors and only 12 (4.80%) to genuine model errors, so a model's measured error rate cannot fall below the instrument's defect rate. (Ansari et al. (2026))
- **Validity and measurement.** Construct validity is often thin: proxies for "learning," "engagement," or "literacy" vary widely, and instruments are not always validated for the population or construct being studied. Benchmark accuracy does not equal educational effectiveness.
- **Self-report and survey data.** A large share of the corpus relies on self-reported attitudes, motivation, and usage. Self-report is subject to bias — respondents overestimate competence, under-report misuse, and misjudge their own behavior — so perception-based measures frequently diverge from objective performance (see How to Assess AI Literacy: Misalignment Between Self-Reported and Objective-Based Measures and Educational Measurement).
- **Context and validation reporting can be quantified across a literature.** A PRISMA-ScR review of 421 studies of NLP on teaching-evaluation comments found country unresolved in 221 studies, single-institution scopes in 232 of 284 resolved cases (81.7%), external validation in 33 (7.8%) and inter-annotator agreement in 54 (12.8%) (Eicher & da Silva (2026)).
- **Reporting richness is measurable, and method type predicts it.** In 888 review-automation papers, 38.0% of software/product papers since 2023 reported no evaluation against 9.3% of LLM papers, and 52% of 118 positive-only LLM papers still flagged an unmet reliability bar — the pattern behind PRISMA-LLM's five disclosure tiers (Zabaleta & Lin (2026)).
- **Standardizing within each dataset can hide a misstatement of spread.** When synthetic educational cohorts were standardized by their own dispersion, the fact that their weekly structure varied 2.6 to 4.9 times less than the real cohorts' became invisible to the reported statistics - routine preprocessing, in the authors' words not a hypothetical worry (Inoue & Yasutake, 2026).
- **Model-generated labels are not ground truth.** Where the labels that train or evaluate a system are themselves produced by language models, agreement between annotators cannot establish validity: Bernado et al. (2026) never validated their assertion annotations against human gold labels, and the 49 encoder classifiers they release inherit that provenance and may not be valid where applications differ in significant dimensions. Their schema also strictly underperformed the fine-tuned classifier trained on expert-annotated data (macro-F1 0.673 against 0.76), leaving expert-labeled corpora worthwhile when high confidence is required.
- **The evidence base itself is unevenly distributed.** A scoping review of 407 technology-supported formative assessment studies drew only on Web of Science and Scopus. It also excluded 61

records on language criteria, so the geographic imbalance the field reports may partly reflect which venues are indexed (Bulut, 2026).

The speed problem: AI evolves faster than findings

AI is changing continuously, and the conclusions drawn from any given model or system can become **out of date quickly**. A study of one Large Language Models (LLMs) generation may not describe the next; benchmark scores, tutoring quality, and even the practical usefulness of a finding shift as models improve. Compounding this, the **publication process is slow** — from study design to peer-reviewed publication can take a year or more — so a published result may already describe an obsolete system. Reviewers and readers should therefore treat AIED findings as provisional, date-sensitive claims rather than stable truths, and prefer recent, replication-oriented, and version-explicit work.

Thoeni and Fryer (2026) make the consequence concrete for one literature: because RAG-based systems only became publicly available in November 2023, they argue that pre-2023 intelligent tutoring findings — resting on rule-based, keyword-matching or heuristic NLP systems that bear little functional resemblance to current large language models — should be treated as historical context rather than directly comparable evidence, and report that their review found no published RCT examining a RAG-based AI chatbot in undergraduate education over a full academic term. The implication is that foundational questions about how genAI affects learning may need to be re-asked against each new model generation rather than settled by pooling older results.

Research-practice limitations

Several limitations concern the conduct and infrastructure of the research itself:

- **Lack of reproducibility.** Studies often do not report enough detail (prompts, model versions, hyperparameters, data, analysis code) for others to reproduce or verify results — a particular problem given how sensitive LLM output is to prompts and settings.
- **FAIR research practices.** Open and reproducible practice — **F**indable, **A**ccessible, **I**nteroperable, **R**eusable data and code, pre-registration, and shared benchmarks — is unevenly adopted in AIED. Weak adherence to FAIR principles makes it harder to reuse, compare, and build on studies.
- **Proprietary tools and models.** Much research depends on closed, proprietary AI systems whose internal behavior, training data, and model updates are opaque and may change without notice. This limits reproducibility, makes exact replication impossible, and can tie findings to a vendor's roadmap. It also raises questions about evaluation independence (see AI Ed Evaluation).

Weak or limited theory use

A recurring criticism is that many empirical articles have **limited or outdated theoretical framing**. Researchers may:

- **Adopt theories uncritically.** Frameworks are borrowed because they are familiar, without fully engaging their assumptions, scope, or evidence base.

- **Misinterpret frameworks as fixed sequences.** Several widely used frameworks are treated as ordered ladders that learners must climb from a "low" to a "high" stage — but the evidence does not support always starting at the bottom. For example:
    - **Bloom's taxonomy** is often read as a strict hierarchy (recall → application → evaluation), yet higher-order goals do not require first drilling lower-order ones; tasks can be designed to engage evaluation or creation from the start (see Cross-Dataset Bloom Question Classification: Supervised Models and Prompted LLMs).
    - **ADDIE** and other instructional-design models are sometimes treated as rigid linear phases rather than the iterative, flexible planning heuristics they are meant to be (see Learning Design).
- **Overlook contested theories.** Some theories used widely in AIED have themselves been challenged. **Cognitive load theory**, for example, has been criticized and its empirical claims refuted or disputed in prior studies, yet it continues to be invoked as a settled foundation in new AIED work.

The implication is not that theories and frameworks are useless, but that they should be used with attention to their actual evidence base, their intended scope, and their known criticisms — rather than as self-evident scaffolds or rigid procedural sequences.

The meta-analytic evidence crisis

A growing body of meta-research — reviews that scrutinize the reviews — argues that the field's headline claims of AI-driven learning gains rest on an evidence base that is far weaker than it appears. Three complementary critiques make the case with unusual force:

- **Positive-synthesis bias is severe and quantifiable.** Bartoš et al. (2026), in a study-level meta-meta-analysis of 1,840 effect sizes from 67 meta-analyses, found strong evidence of publication bias (all Egger tests $p < .0001$) and extreme between-study heterogeneity ($\tau = 0.869$). Publication-bias-adjusted effects were roughly **one-third** the magnitude commonly reported (SMD = 0.196 vs. a median of 0.67 in the published literature), with a prediction interval spanning −1.521 to +1.908 — from large harm to large benefit. No outcome, field, level, or AI-role subgroup showed consistent gains, and there was no difference between pre- and post-2023 studies. Their verdict: broad claims of generalized learning gains are premature.
- **Meta-analytic methods are being systematically misapplied.** O'Neill (2026)'s forensic audit of 14 high-impact AIED meta-analyses found that *none* provided a valid basis for their claims: none had a coherent construct (treating the tool "ChatGPT" as if it were a single intervention, and pooling test scores, motivation, Self-Efficacy, and attitudes into one "academic achievement" number); reported heterogeneity was severe, with I^2 ranging from 77.2% to 94.4% across the 13 meta-analyses that reported it and 12 of those 13 above 80%, and it was never resolved (none met the minimum subgroup size of ten studies, five relied on single-study subgroups, and three others on subgroups of two); twelve treated dependent effect sizes from the same study as independent, inflating apparent evidence; and none validly assessed publication bias (discredited fail-safe N metrics and misapplied Egger tests were common). Because I^2 is precision-dependent it cannot by itself establish how far apart the true effects are, and the reporting that would show it was largely

absent: only four meta-analyses reported between-study variance (τ^2) and only two reported a prediction interval, both of which included zero. A majority (61%) of randomly vetted primary studies were problematic, and one study with fabricated references was included by six of the 14 meta-analyses.

- **The "treatment" is a black box.** Weidlich et al. (2025) revive the media/methods debate to argue that "ChatGPT" is a tool, not a method — asking whether it "improves learning" is a non sequitur. Auditing a subset of the studies behind Deng et al.'s (2025) meta-analysis, they found only 21% of comparisons had a well-defined treatment, control group, *and* valid learning measure; reported effect sizes (g = 0.7) even exceeded those of purpose-built Intelligent Tutoring Systems (0.66), a red flag that the "treatment" was a heterogeneous "secret sauce."

The convergence of these three independent critiques is itself evidence: across different methods, corpora, and framings, they reach the same conclusion — that positive AIED effect sizes, especially from early meta-analyses, likely reflect **publication bias, construct incoherence, and methodological shortcuts** as much as (or more than) genuine learning gains. This does not mean AI tools have no educational value; rather, it means the *field-level* evidence for their value is currently inflated and must be read accordingly. It also shifts responsibility to synthesis quality: a meta-analysis is only as trustworthy as the coherence of its constructs, the independence of its effect sizes, the adequacy of its moderator and heterogeneity analysis, and the validity of its publication-bias assessment — each of which the critiques show is routinely violated.

Reading the AIED literature critically

Taken together, these limitations argue for a critical, multi-signal reading of AIED research: check whether a finding generalizes and is adequately powered; verify how constructs were measured (and whether claims rest on self-report); prefer recent, version-explicit, reproducible work; and interrogate the theoretical framing rather than treating familiar frameworks as given. This is the complement of rigorous method choice and evaluation: good methods and good evaluation are necessary, but reading with attention to limitations is what turns evidence into defensible decisions.

From research to practice

A further, practical limitation is the **challenge of applying research to teaching and instructional design**. Practitioners — instructors, instructional designers, and faculty developers — often lack the time or specialized expertise to read, appraise, and translate primary research into concrete classroom decisions. The literature is large, fragmented, and written for researchers; findings are reported with statistical and methodological detail that is not immediately actionable; and because claims are provisional (see the speed problem above), a practitioner cannot simply take a single study at face value. This creates a gap between what the evidence supports and what actually reaches teaching practice.

The purpose of this knowledge base is to help close that gap — to make it easier to keep up with, interpret, and apply AI-in-education research to practice — by curating open-access findings into structured, accessible summaries, connecting related work through concept pages, and flagging the limitations readers should weigh. It aims to support evidence-informed practice in teaching and instructional design, and in doing so to also surface gaps and questions that can inform new research and development. Understanding

the limits of the research is therefore not an end in itself: it is what lets practitioners apply findings appropriately and lets researchers design stronger studies that better serve practice.

Two Audit Traps Worth Knowing

Two specific reporting practices inflate or distort a synthesis, and both are visible in the published record rather than hypothetical.

The heterogeneity figure depends on the model, and the model is rarely quoted. One review's heterogeneity is quoted as **I^2 = 82.98% under a fixed-effect model and I^2 = 15.75% under the random-effects model**. Those describe the same data. A reader who lifts a single heterogeneity number without its model has been given a technical claim with no interpretation attached, and the difference between "most variance is unexplained" and "little variance is unexplained" is the difference between discarding and trusting the field.

The headline percentage can be an artifact of the search terms. A scoping review of 195 teacher-education studies made digital competence and TPACK explicit search descriptors, while instructional design and assessment had no equivalent term, so the reported **46.5% and 1.9%** are rates the query itself constructed. A prevalence claim is only as meaningful as the search behind it.

And the base rate is the number nobody states. Methodological limits here are measurable rather than impressionistic: in a critical review of 80 HCI studies of critical thinking with AI, **42 (52%) ran no control group** and most of the rest relied on self-report. When more than half of a field's positive findings come from designs that cannot separate AI's effect from ordinary activity, the appropriate prior on any single finding is skepticism, not provisional acceptance.

Common Misconceptions

- **"Limitations sections are boilerplate."** Methodological limits are **measurable rather than impressionistic**: in a critical review of **80 HCI studies** of critical thinking with AI, **42 (52%) ran no control group**. A precise count is what makes the limit actionable.
- **"Heterogeneity is a single number you can quote."** The same review shows a reporting hazard: heterogeneity is quoted as **I^2 = 82.98% under a fixed-effect model and I^2 = 15.75% under the random-effects model**. The same data yields a nine-point story or a two-point story depending on the model chosen, so a quoted I^2 without its model is uninterpretable.
- **"A large reported effect is the number to trust."** A headline like an effect from **30 students in one course at one site** is the common form of a fragile claim, and the count of studies without controls shows how often that fragility goes unreported.

Philosophy of AI in Education

> **Philosophy of AI in Education** — the branch of educational philosophy that examines the fundamental conceptual questions raised by artificial intelligence in teaching and learning: What is the nature of knowledge and thinking when machines participate in them? What is the learner when cognition is distributed across human and artificial systems? What forms of Learner Agency, responsibility, and personhood apply to AI, and what does education owe learners in an AI-mediated world? Distinct from (but connected to) the knowledge base's Learning Theories page, which catalogs theories of *how learning happens*, the philosophy of AI in education asks the deeper questions of *what learning, mind, and the learner fundamentally are* under AI-mediated conditions.

Questions to Consider

- Does thinking require consciousness and a body? If an AI genuinely participates in your reasoning, is some of the 'thinking' happening in the machine—and does that change who's learning?
- The page raises the idea of cognition 'distributed' across human and artificial systems. Think of a task you've solved with AI help: where did your thinking end and the machine's begin?
- If a learner's cognitive processes become genuinely hybrid (part human, part artificial), what does that mean for what we call 'the learner'—and for what education owes them?
- The page distinguishes philosophy (what learning and the learner fundamentally are) from learning theories (how learning happens). Can you name a belief you hold about learning that is really a philosophical position?
- If AI can exercise 'functional agency' without consciousness, does it bear responsibility for its educational effects—and if not, who does? Who should answer when an AI tutor misleads a student?
- Posthumanist thought reframes learners as 'post-human' entities. How does that idea challenge or unsettle your own assumptions about where a student's mind is located?

Introduction

This is a concept page for the philosophical and theoretical foundations of AI in education. While Learning Theories documents the empirical and design-oriented theories (Behaviorism, constructivism, cognitive load, self-regulated learning, etc.), the philosophy strand engages the ontological, epistemological, and ethical questions those theories presuppose. The two are closely connected: philosophical positions shape which learning theories seem plausible and which educational goals are worth pursuing.

Key philosophical questions

- **The nature of mind and cognition.** Does thinking require consciousness and a body? Can AI participate in genuinely cognitive processes? Frameworks such as **ensemble cognition** argue that

AI exercises *functional agency* — genuine causal efficacy in cognitive processes — without consciousness, and that thinking emerges from dynamic human–AI interaction.(Towards a philosophy of ensemble cognition: Reconceptualising agency and mind in AI-mediated educational environments) Distributed cognition and the extended mind thesis make related claims about cognition being spread across systems.

- **What is the learner?** Posthumanist philosophy reconceptualizes the learner as a "post-human" entity whose cognitive processes are genuinely hybrid and distributed across biological and artificial systems.(Pedagogical Symbiosis: conceptualizing the Post-Human Learner in the age of cognitive AI) This challenges the assumption that the learner is a bounded, autonomous individual mind.
- **Embodiment and the limits of disembodied AI.** Embodied and post-cognitivist philosophy critiques the dominance of symbolic, disembodied AI models, arguing that cognition is grounded in situationality, emergence, and sensorimotor coupling that current generative AI lacks.("If You Can't Dance Your Program, You Can't Write It": Challenges and Implications for AI in Education)
- **Agency, authorship, and meaning.** When AI mediates interpretation and meaning-making, philosophy asks how authorship, epistemic Learner Agency, and interpretive autonomy are reconfigured.(AI-Mediated Learning and the Restructuring of Interpretive Cognition: A Developmental-Critical Model for Social Sciences and Humanities Education)
- **The ontology of AI-generated scientific objects.** In chemistry, AI-predicted compounds and titration curves occupy a "liminal ontological space" — neither wholly hypothetical nor fully real until empirically proven — which shifts the discipline from realism toward a constructivist view in which reality is a collaboration of human and machine (Reyes and Regala (2026)).
- **Cognitive passivity as an epistemic harm.** Bai and Costa (2026) draw on Arendt's account of thinking as an inward, untransferable activity to argue that GenAI which supplies the work does not merely offload thinking but forecloses it, with Bourdieu's field and habitus locating the risk in institutional structures (Bai & Costa (2026)).
- **Values, justice, and the purpose of education.** Philosophical analysis examines whether AI-driven education serves human flourishing and educational justice, or whether it instrumentalises learning in service of productivity.(Can we disrupt the momentum of the AI colonization of science education?) This connects to Critical Pedagogy and Ethics.
- **'Human-centered' as an anthropocentric discourse, not a neutral ethic.** Wang & Jin (2026) read UNESCO, OECD and Montréal Declaration documents to argue that human-centered AIED inherits Enlightenment humanism's exclusions, that transhumanism preserves them, and that the label can legitimize commercial infrastructure.
- **Epistemological grounding for how people engage AI.** Strydom (2026) derives seven human–generative-AI engagement paradigms from Schommer's five dimensions of personal epistemological belief (source, certainty, organization, control, and speed of knowledge) and argues they are enacted rather than possessed — so shifting how learners engage AI requires changing the socio-technical environment, not their beliefs.

- **Whose philosophy? Pluralism in the field's conceptual foundations.** Xie (2026) argues that the field's philosophical debate is over-determined by a single Western architecture — epistemic agency as a property of discrete subjects, knowledge framed representationally and calculatively, and the human–AI relation located within subject–object dualism — so that its limits become the limits of the field's collective imagination. As a comparative counterweight he reconstructs Daoist concepts — "Dao nature" (道性), self-cultivation (修道) and the "Zhenren" (真人) — not as "Eastern content" added to an unchanged frame but as resources that reshape the conceptual foundations through which AI itself is understood, applying them to knowledge (epistemic monoculture and synthetic misinformation), knowing (offloading that degrades critical thought) and impact (environmental costs and Global North–South asymmetries).(Alternative AI Philosophy: Daoism as Method for AI in Education)
- **Agency without answerability.** A corpus-assisted discourse analysis of 366 GenAI higher-education abstracts finds AI named 2,050 times and entering 447 strict actor–predicate associations - the field's most frequent actor - yet action predicates dominate them (78.7%) and no sentence makes a system responsible: of 166 obligation expressions, none assigned responsibility to a system, and the single clause linking AI to accountability says AI is not accountable. Poudyal (2026) reads this as functional agency recognized in language without the relational responsibility that would attach it to anyone. **Neither tool nor collaborator: the mediational agent.** Warschauer, Tate and Ritchie (2026) argue that calling generative AI a mere tool understates its interactional influence while calling it a collaborator wrongly grants it intentionality and accountability, and propose the *mediational agent* — a responsive, non-accountable system whose novelty is participation rather than intelligence.

Relationship to learning theories

The philosophy of AI in education and Learning Theories are complementary lenses. Learning theories explain the mechanisms of learning (e.g., how Feedback, Scaffolding, or cognitive load shape outcomes); philosophy interrogates the presuppositions of those mechanisms — what counts as knowledge, who counts as a knower, and what the learner fundamentally is. Posthumanist and critical-philosophical work, in particular, challenges the field to move beyond instrumentalist frameworks like Technological Pedagogical Content Knowledge (TPACK) and SAM toward deeper ontological reorientation.(Pedagogical Symbiosis: conceptualizing the Post-Human Learner in the age of cognitive AI)

Relationship to theory development

Philosophy of AI in education and theory development in AIEd are complementary but distinct. Philosophy asks the ontological and epistemological questions — what mind, knowledge, and the learner fundamentally are under AI-mediated conditions — while theory development produces and empirically tests the *mechanisms* that operationalize answers to those questions (generativism, epistemic co-agency, the absent cognitive baseline). The two are mutually informing: philosophy clarifies the presuppositions that theories carry (e.g., epistemic co-agency presumes a distributed, non-individualist model of cognition), while theory development gives philosophical positions testable, falsifiable form. The field's most foundational articles do both at once, sitting at the boundary between the two concepts.

Common Misconceptions

“The philosophy of AI in education is the same as cataloguing learning theories.” They sit at different depths. The Learning Theories page asks *how learning happens*; the philosophy asks *what learning, mind and the learner fundamentally are* under AI-mediated conditions. A study can settle a learning-theory question and leave the philosophical one untouched, which is why a technically successful intervention can still be the wrong thing to do.

“Cognitive offloading is the harm, and it is reversible by more effort.” There is a stronger claim available. Bai and Costa (2026) draw on Arendt’s account of thinking as an inward, untransferable activity to argue that GenAI which *supplies* the work does not merely offload thinking but forecloses it — and they locate the risk institutionally, through Bourdieu’s field and habitus, rather than in individual willpower. If the argument holds, “use it carefully” is not a sufficient remedy, because the practice is shaped by the field that rewards the output.

“Non-Western philosophy is content to add to an unchanged frame.” It can be a source of different foundations. One reconstruction treats Daoist concepts — “Dao nature” (道性), self-cultivation (修道) and the “Zhenren” (真人) — not as “Eastern content” appended to a Western framework but as resources that reshape the conceptual foundations through which AI in education is understood. Adding a tradition as illustration and using it to reframe the questions are different scholarly acts.

“Philosophical critique is unactionable.” It sets what counts as success. Whether a system’s output is a learner’s achievement, and whether a measured gain is an educational good, are prior questions that no effect size can answer — and institutions that skip them will optimize the measurable and call it improvement.

Implications for Practice

For instructors

- Decide, before you adopt a tool, what you are willing to count as the student’s own achievement. If a polished submission produced by the system would satisfy your assessment, you have answered “nothing” — and no later rubric change recovers the question.
- Treat the foreclosing argument seriously when designing tasks: if GenAI that supplies the work forecloses thinking rather than merely offloading it, then “use it responsibly” is not a sufficient safeguard, because the surrounding field rewards the output. Design tasks whose evidence of thinking is produced before the tool is available.
- Ask whose conception of learning your course encodes. Adopting a framework uncritically imports its assumptions about what a learner is, and those assumptions are contestable.

For developers

- Expose the boundary you have drawn between assistance and supply, and make it a product decision rather than a default. A system that can produce the finished artifact has decided, implicitly, that mental work is optional.
- Resist optimizing for the appearance of learning. Fluency and completeness are the measurable properties, and they are the ones that mask foreclosure.

- If you claim your system “supports thinking”, state what it refuses to do — the refusal is the mechanism.

For researchers and policymakers

- State the conception of learning your evaluation presumes, because a measured gain is only an educational good relative to some account of what education is for.
- Fund the philosophical work alongside the empirical work: questions about what counts as a learner’s achievement set the success criteria the empirical studies then use.

Theories and Frameworks

> **Theories and frameworks** — the working inventory of explanatory and organizational structures this knowledge base actually uses. Theories explain why learning happens (Learning Theories, Self-Determination Theory, Sociocultural Learning, activity theory); frameworks organize design, teaching, and adoption decisions (Technological Pedagogical Content Knowledge (TPACK), SAMR, technology adoption models, ICAP, universal design for learning); models make learning claims testable and computable (item response theory, Assessment Validity, Knowledge Tracing). Use this page to find the lens a study rests on, or to pick one for your own work.

Questions to Consider

- A theory predicts what happens when something changes; a framework tells you what to attend to. When a study reports a gain under a framework's banner but makes no prediction that could have failed, what has actually been learned?
- TPACK, SAMR, UDL, the adoption models and ICAP all predate large language models. Which parts of them still hold when the tool can write, explain, and adapt on its own, and how would you tell?
- Several of the theories catalogued below were coined for AI within the last few years. What would it take for one of them to be wrong, and has anyone tried to show that?
- Adoption is often reported as movement through stages. If a colleague reports that their course moved "from substitution to redefinition" this year, what independent evidence would you ask for before believing it?
- Much of this field applies borrowed theory rather than testing it. Pick a finding you rely on: could it be reframed as a test of a theory, and what measurement would that require?

Introduction

Every AI tutor, feedback system, and dashboard embeds assumptions about how people learn, whether or not the designers state them. This page collects the theories, frameworks, and models those assumptions come from, ordered loosely by how much of the current research literature leans on them, and says briefly what each one is good for. The distinctions among the three labels are real but minor, and they are summarized near the end rather than treated as the subject. What matters practically is which lens a claim rests on, and whether that lens can support the claim.

Learning theories the literature applies

These explain mechanisms: they name the parts that do the work and predict what follows when those parts change. In the AI literature they are mostly borrowed from psychology and the learning sciences, and used as interpretive frames around a new tool.

- **Learning theories (umbrella)** — the family as a whole, including the classical poles of Behaviorism and constructivism and the "constructivism in name, behaviorism in practice" gap that recurs in AI implementations. Connectivism and cognitive load theory are covered here too.
- **Constructivism** — learning as active knowledge construction. It underwrites project-based work, dialogue-based AI tutoring, and the critique that drill-and-feedback systems violate their own stated pedagogy.
- **Sociocultural theory** — learning as mediated by tools and social interaction, which is why AI gets theorized as a mediating artifact rather than a mere aid.
- **Activity theory** — takes the whole activity system, contradictions included, as the unit of analysis. Common in teacher-facing AI studies, where the interesting finding is usually the tension among tools, rules, and community.
- **Situated learning** and **Embodied learning** — learning as tied to context and to the body, the counterweight to treating AI as a purely linguistic medium.
- **Distributed cognition** — thinking spread across people and artifacts, which frames AI assistance as a redistribution of cognitive labor rather than a substitution for it.
- **Community of inquiry** — the social, cognitive, and teaching presences that make an online experience work; a theory of the experience and a design frame at once.
- **Self-determination theory** — autonomy, competence, and relatedness as motivational preconditions. Often the explanation offered when AI use raises engagement without raising learning.
- **Cognitivism** — information processing, working memory, and the divergence between the feeling of learning and actual learning.
- **Social perception theory (warmth and competence)** — imported from social cognition and service-robot research, it frames how users judge an AI agent's credibility: perceived competence predicted ChatGPT's feedback credibility directly while warmth worked only through human-like empathy (SEM, 230 students; Pérez-López et al. (2026)).
- **A fourth affordance category was proposed, not tested.** Coding 24 studies against a three-part affordance scheme, the reviewers found engagement, safety and self-efficacy did not fit the technological, pedagogical or social categories, and proposed emotional affordances grounded in Bandura's reciprocal determinism (Lopez & Arabadzhy (2026)).

Models of the learner and of the learning process

- **Self-regulated learning** — planning, monitoring, and evaluating one's own learning. The workhorse construct for asking whether AI support reaches the phases that matter or only execution.

- **Metacognition** — thinking about one's own thinking, and the construct most often named when AI is accused of doing the thinking for students.
- **Motivation** — why learners engage, and the construct that separates engagement from learning in AI studies.
- **Self-efficacy** — belief in one's capability, distinct from competence, and a frequent mediator between AI use and outcomes.
- **Agency** — who directs the work: the construct behind the field's control-versus-autonomy tension, and behind the delegated-agency mechanism in the newest theory.
- **Desirable difficulties**, **retrieval, spacing, and interleaving**, and **refutation text** — findings that make friction pedagogically valuable, applied to decisions about how much an AI should do.
- **Transfer of learning** — whether capability persists once support is withdrawn, which recent theory treats as the criterion separating learning from assistance rather than one outcome among several.

Teaching, integration, and adoption frameworks

- **TPACK** — the teacher knowledge that blends technology, pedagogy, and content; the default framework for teacher-facing AI studies.
- **Adoption models** — intention as a function of perceived usefulness and ease of use. Used widely enough that the field's reliance on intention rather than behavior is a standing critique.
- **ICAP** — ranks engagement as passive, active, constructive, interactive; useful for asking what mode an AI interaction actually affords.
- **SAMR** — substitution through redefinition. Popular as a maturity story, weak as a measurement instrument.
- **Universal design for learning**, **inclusive learning**, and **Accessibility** — design frames for who gets served, and the ones most often invoked in disability and equity work.
- **Learning design**, **Curriculum design**, and **Design thinking** — how tasks, sequences, and programs are structured before any tool is chosen.
- **Change management** — whether a system is taken up at all, which is usually an institutional question rather than a pedagogical one.

Measurement and computational models

- **Item response theory** — item and ability estimation, and the model that makes a test's numbers interpretable.
- **Educational measurement** — the instrument landscape, including the measures built specifically for AI literacy.
- **Validity** — whether an instrument measures the construct it claims, which decides whether a reported outcome supports the theoretical claim attached to it.
- **Self-report measures** — the dominant and most fragile source of evidence in this literature; several constructs above are known to diverge sharply between self-report and performance.

- **Knowledge tracing** and **Student modeling** — estimating a learner's state over time from interaction data.
- **Cognitive diagnosis** — attributing performance to specific skill components, the modeling counterpart to diagnostic teaching.
- **Benchmarks**, **AI education evaluation**, and **psychometric awareness in AI design** — how systems and interventions are scored, compared, and audited.
- **Design-based research** — the method that generates theory from designed interventions rather than testing it in advance.

Theories coined for the AI era

Four proposals in the knowledge base build theory rather than borrow it. They are article pages rather than concept nodes, because each one is a single argument:

- **Generativism** — a new learning theory arguing that the classical four show significant conceptual limitations as generative AI proliferates.
- **Epistemic co-agency** — a model of how learners and AI systems jointly produce knowledge and understanding.
- **The absent cognitive baseline** — theorizes why AI-native students overestimate their own learning when AI inflates performance.
- **Agentivism** — a mid-range theory naming four mechanisms (delegated agency, epistemic monitoring and verification, reconstructive internalization, and transfer under reduced support) and stating six testable propositions.

Telling the three labels apart

The words are used loosely in the literature, and the difference is worth one paragraph rather than a whole page:

- **A theory explains a mechanism** and predicts what happens when its parts change. It can fail, which is why studies that test one can report effect sizes.
- **A framework organizes or prescribes.** It names the components to attend to, usually without predicting magnitudes, and it cannot be falsified.
- **A model is a formal representation**, most often of measurement or of the learner's state. It can be fitted, compared, and shown to be wrong in a way a framework cannot.
- **The labels overlap.** Community of inquiry is a theory and a design frame at once; activity theory is explanatory and analytic. Treat the label as a clue about what a source claims, not as a filing category.

Related layers

Two neighbouring pages are deliberately about something else. Philosophy of AI in education asks normative and conceptual questions — what education is *for*, whether a machine can teach — and does not predict effect sizes; a study can be philosophically naive and theoretically sound, or the reverse. Theory

development is the meta-activity of building, borrowing, and revising theory, including the standing critique that much AIED work applies existing theory rather than testing it. This page is the inventory; theory development is about producing and revising the inventory.

Choosing a lens when the question is practical

- **Instructors** starting from a problem can work backwards: if learners are not engaging, ICAP and SDT name different causes and suggest different fixes; if the question is whether to adopt a tool at all, adoption models and SAMR ask different things about it.
- **Learning designers** get the most from the design frames — UDL, Learning Design, and Scaffolding — paired with a theory that predicts what happens when the scaffolding is removed.
- **Researchers** should state which node a study claims and whether the design can actually test it; the measurement models (IRT, Assessment Validity, Self-Report Measures) decide whether a reported outcome supports that claim.
- **Administrators** meet these frameworks as adoption and change questions, where a stage model is often used as a maturity story rather than an instrument.

What frameworks cannot do

Frameworks are not evidence. They are usually borrowed from pre-LLM contexts and localized by whoever applies them, they can function as branding, and stage models invite checkbox adoption that reports movement through levels rather than learning. Claims resting on a framework should be read alongside the field's cross-cutting limitations, the validity of whatever measured the outcome, and the known limits of self-report.

Mechanism-to-theory alignment can nonetheless be decisive: a thematic synthesis of 55 AI-supported game-based learning studies found effectiveness turned on whether the AI mechanism enacted the pedagogy it was meant to serve rather than on algorithmic sophistication (Kaşarcı and Yurt (2026)).

Common Misconceptions

"Applying a borrowed theory to an AI tool is using theory." Much of this field applies borrowed theory rather than testing it, and the difference is whether the framework made a prediction that could have failed. When a study reports a gain under a framework's banner while committing to no falsifiable prediction, nothing has been learned about the framework — an outcome consistent with every theory in the catalog is evidence for none of them.

"A framework's value is how well it describes a system you have already built." That is post-hoc labeling. A taxonomy that accommodates any design has no discriminating power, which is why descriptive frameworks should be judged on what they exclude. The evaluation question is not "does my system fit this?" but "what kind of system would this framework say is wrong?"

"Learning theories, models of the learner, and adoption frameworks are interchangeable lenses." They answer different questions — how learning happens, what the learner's state is, and why a practice spreads

— and their evidence types differ accordingly. Choosing the wrong layer produces a study that measures the right variable against the wrong prediction, which reads as a null result when it is a category error.

“More frameworks means a more mature field.” Coined-for-the-AI-era frameworks accumulate faster than they are tested, and accumulation without falsification is a symptom rather than progress. Maturity shows up as competing predictions being resolved, not as vocabulary growth.

Theory Development in AI in Education

> **Theory development in AI in education** — the scholarly work of creating, advancing, and critically examining the theories and conceptual frameworks that explain how learners, teachers, and AI systems interact. As generative AI reshapes education, the field is both proposing *new* theories of learning-with-AI and reworking established learning theories — while a documented weakness in theory use remains a cross-cutting limitation of AIEd research.

Questions to Consider

- We often talk about 'applying a theory' to AI in education, but this page asks whether the field is actually inventing new theories. Before you read on: when a familiar framework (like Behaviorism or constructivism) is stretched to cover generative AI, what might it get right, and what might it silently distort?
- Consider a time you used AI and felt your understanding grew — or the opposite. What is the difference between 'learning with a tool' and 'co-constructing knowledge with a machine'? Where would you draw that line, and does it even make sense to say the machine is a co-agent?
- Many AI education studies are criticized for using theory weakly or not at all. If you read a study that showed an AI tool 'worked,' what would it need to tell you about why and how it worked before you would call the finding theoretically meaningful rather than just an effect size?
- One proposed theory claims AI-native students overestimate their own learning because AI inflates their performance. Have you noticed yourself or others feeling more competent after heavy AI use than you could actually demonstrate without it? What would be the strongest evidence that this is a real phenomenon and not just an artifact of one study?
- The page distinguishes theory (explaining mechanisms of learning) from philosophy (questioning what learning and mind fundamentally are). Where in your own thinking about AI do you find yourself moving between the two — for instance, asking not just whether a framework explains learning well, but whether it captures what learning really is?
- New theories are appearing — generativism, epistemic co-agency, cognitive commons. As a reader, what would convince you that one of these is a genuine advance rather than a fashionable relabeling of older ideas? Set your own test for what a good new theory of learning with AI should be able to explain.

Introduction

Theory development in AIEd sits at the boundary between the applied learning theories the field draws on and the novel constructs the AI era is producing. Where Learning Theories catalogs the established theories applied to AI (behaviorism, constructivism, cognitive load, self-determination, etc.), this concept tracks the *process and product of theorizing itself*: which new theories and frameworks are being born, how established theories are being advanced, and the methodological question of whether AIEd research theorizes well. - **A framework that specifies its own comparison condition.** Nakamura (2026) treats the partition of cognitive

labor as the explanatory unit, places operations on a graded peripheral–constitutive continuum, names the comparison condition against which augmentation and erosion are defined, and derives seven conditioned testable propositions (Nakamura, 2026). Because the propositions predict differences between configurations, a study reporting only an average effect cannot confirm or refute them.

New theories of learning with AI

A growing cluster of articles explicitly creates new theory for the AI era rather than applying existing frames:

- **Generativism.** Generativism is proposed as a new learning theory, arguing that behaviorism, cognitivism, constructivism, and connectivism each rest on one assumption that generative AI breaks: that observable output certifies learning (behaviorism), that cognitive operations happen inside the learner (cognitivism), that meaning is constructed rather than supplied (constructivism), and that the hard part is navigating to existing knowledge rather than generating it (connectivism). It names four constructs — epistemic partnership, distributed agency, generative literacy, and adaptive metacognition — and derives an assessment indicator for each, a direct bid to name a distinct theoretical paradigm for AI-mediated learning. What it does not do is state propositions that could fail: it is a position paper synthesizing existing evidence, so unlike Agentivism below it offers a vocabulary and a measurement agenda rather than a falsifiable theory.
- **AI connectedness.** Fu and Zhao (2026) reconstruct connectedness for the AI era through the ethics of care and neo-ecological theory, defining "artificial intelligence connectedness" as a psychologically real yet ethically asymmetric bond with three dimensions and six falsifiable propositions awaiting scale development.

The synthetic position adds a rival bid that does state propositions: it names *synthetic promotion* and *authorial suspension* — a self densely voiced yet un-authored — and predicts a crossover interaction in which a life-decision narrative's rated authorship and coherence move in opposite directions (Du et al. (2026)). - **Agentivism.** Yan and Gašević (2026) propose Agentivism as a mid-range learning theory for human-AI interaction, defining learning as durable growth in human capability rather than successful task completion with AI, and specifying four mechanisms: delegated agency, epistemic monitoring and verification, reconstructive internalization, and transfer under reduced support. What separates it from the other bids on this page is falsifiability: it states six propositions, including that learning is stronger when AI preserves learner responsibility for problem framing, criteria setting and justification than when it supplies answers. It also holds that requiring verification should improve delayed performance while repeated low-friction delegation without reconstruction should weaken learners' calibration of their own competence.

Teacher-side theorizing now makes the same testability commitment: the Capability–Decision Model orders AI-TPACK capability upstream of attitude and perceived behavioral control and names four disconfirmation conditions — mediation failure, discriminant collapse, moderation nullity and context redundancy — though the model remains untested (Mnguni (2026)).

- **Epistemic co-agency.** Learning with Machines builds "toward a theory of epistemic co-agency," a theory-informed model of how learners and GenAI systems jointly produce knowledge and understanding.

- **Cognitive partnership cycle.** Page (2026) proposes the Cognitive Partnership Cycle, a six-phase recursive model — Human Question, AI Expansion, Human Reflection, Integration, Revision, and New Question — that locates learning in a change in the learner's cognitive position rather than in prompt sophistication, and names four failure modes where the same recursion substitutes for or distorts thinking.
- **The absent cognitive baseline (ACB).** The Absent Cognitive Baseline theorizes a structural gap in AI-native students' academic Self-Assessment — a three-dimension framework explaining why students overestimate their learning when AI inflates performance.
- **The cognitive commons.** Cognitive commons and expertise regeneration draws on common-pool-resource theory and distributed cognition to explain how rational AI adoption decisions can deplete the shared expertise pool professions require for renewal.
- **Performance vs. learning.** Performance-vs-learning theorizes the sharp divergence between AI-inflated task performance and durable learning, a distinction that recurs across the knowledge base's Learning Gains evidence.
- **Epistemic AI literacy (EAIL).** Epistemic AI Literacy reframes AI literacy as a process-oriented epistemic competence centered on how knowledge is constructed and justified when students co-program with generative AI.
- **Tri-System Theory.** Shaw and Nave (2026) extend dual-process accounts with **System 3** — external, automated, data-driven reasoning from AI that can supplement, supplant or suppress System 1 and System 2 — and name **cognitive surrender**, the uncritical adoption of AI output, as its characteristic failure.
- **Cognitive stewardship.** Credential and cognitive stewardship theorizes the institutional responsibility for protecting knowledge and learning in AI-pervasive assessment contexts.
- **Co-AI Regulation in Education and epistemic proactivity.** AI as a cognitive partner in co-regulation integrates executive function, Metacognition, distributed cognition, and sociocultural development into a developmental model; epistemic proactivity theorizes students' agentic stance toward AI in mathematics.
- **Human-GAI engagement paradigms.** Strydom (2026) addresses the field's "theory deficit" by grounding seven enacted human-GAI engagement paradigms (guarded, possibility-focused, augmented, pioneering, symbiotic, values-based, equity) in Schommer's multidimensional model of personal epistemological beliefs — an epistemological, rather than tool-focused, theory of how individuals differently position themselves relative to AI.
- **The Ecological Co-Agency Framework.** Poudyal (2026) argues that generative AI reassigns epistemological authority from teachers to students to machines, and introduces a framework defining co-agency through three interdependent dimensions — relational, regulatory (mapped onto the SRL cycle), and pedagogical (teacher adoption continuum) — all bounded by a non-negotiable condition of human epistemic accountability (contestability, provenance, and non-delegation of moral/intellectual credit). It positions Learner Agency as an *epistemic* design problem rather than a usability concern, giving institutions a more precise language than "balance" for governing GenAI integration.

- **Relational epistemic agency and epistemic dependence.** Du & Yuan (2026) contribute a critical-integrative account of when AI-mediated reliance preserves versus displaces judgment. They operationalize the productive-reliance/harmful-dependence boundary through six diagnostic criteria (contestability, recoverability, transfer, traceability, distributed responsibility, epistemic plurality) and trace four sociotechnical pathways (fluent authority, frictionless delegation, opaque synthesis, institutionalized dependence). Their normative proposal, **relational epistemic agency**, extends relational-autonomy and epistemic-co-agency lines by retaining an explicit asymmetry — AI may shape reasoning without reciprocal responsibility or legitimate authority — while integrating responsibility and epistemic justice at the institutional level. As a theory of learning with AI, it moves the field's question from whether AI helps or harms to which epistemic actions are preserved, transformed, or displaced, and it makes the *design of dependence* rather than mere use the object of pedagogical and institutional intervention.

Advancing established theory

Other work extends existing theory into the AI context rather than founding new paradigms: critical-thinking-paradox work integrates cognitive-load theory with load-reduction instruction into a three-level framework; equitable assessment re-theorizes Assessment under GenAI disruption. Ba, Gašević, Lim & Anderson (2026) reconceptualize the Community of Inquiry framework itself: rather than framing GenAI as a tool, dialogic partner, or a speculative "fourth presence," they reposition it as an *epistemic condition* that reconfigures how cognitive, social, and teaching presence are enacted, evidenced, and governed — recasting CoI presences as sociotechnical accomplishments of human–GenAI assemblages and proposing a configuration-based heuristic in which GenAI involvement and inquiry quality are conditionally related through human accountability. Much of this is conceptual-framework work (business-school frameworks, valid simulation) that operationalizes theory for practice.

Lin and Chang (2026) extend Self-Regulated Learning and human–AI regulation by naming what the learner governs — standards, evaluative judgments, and control authorization — rather than only what the AI does.

The friction paradox offers another extension of established theory: Gupta (2026) applies Bjork and Bjork's desirable difficulties and Kapur's productive failure to relational encounters in education abroad, arguing that what matters is how much interpretive agency a student transfers to a generative assistant rather than how often it is used. The framework is conceptual and states five propositions as competing hypotheses.

Ranieri & Biagini (2026) advance the field's functional taxonomy of Zawacki-Richter et al. (2019): among the 154 publications with a classifiable application function, 90 (58.4%) escaped its four categories, and their framework crosses function with delegated control, epistemic position and embedded pedagogy.

An, McLaren, and Stamper (2026) advance ACT-R and the Knowledge-Learning-Instruction framework by theorizing *deceptive overgeneralization* — a failure mode in which knowledge compilation yields an overgeneralized production that produces correct actions while omitting a critical application constraint — and by empirically validating a detection/remediation procedure across adaptive ITSs and a K-12 decimal-learning dataset.

Postphenomenology and technological mediation. Farazouli et al. (2026) advance the established postphenomenological framework of technological mediation (Ihde 1990; Verbeek 2006, 2011; Rosenberger & Verbeek 2015) into the AI-in-education context. Rather than proposing a new theory, they apply it to

reconceptualize GAI chatbots as *multistable technological artifacts* whose "scripts" (rapid responsiveness, natural-sounding text that can achieve passing grades) mediate teachers' perceptions and reconfigure their practices — unsettling teacher confidence, reshaping what competence means, and pushing teachers beyond instrumental questions of acceptable use toward re-evaluating their role and the meaning of teaching. This is a theory-*advancement* contribution: it demonstrates how a philosophical account of human–technology relations explains the emotional and professional disruption teachers experience when GAI enters established educational practice.

A further framework contribution is Rismanchian & Doroudi's AI×Ed typology, which extends Kahn's (1977) original "three interactions" along two axes — the role of AI (applied tool vs. analogy to human intelligence) and the end user (researcher to learner) — to locate any AIED project. Beyond categorizing the field, it argues for reviving the "AI as an analogy to human intelligence" strand of theory and research, using computational and agent-based models of learning (e.g., their own computational model of the ICAP framework) to bridge contemporary learning theory and computational modeling — a methodological direction the field largely abandoned when it turned toward applied, data-driven work.

Comparative philosophy as a route to theoretical pluralism. Xie (2026) models a different route to theory development: instead of theorizing AI in education from within one tradition, the paper stages a comparative dialogue in which each tradition "renders visible what the other obscures," explicitly declining to synthesize them into a single framework — an approach that treats theoretical pluralism as a methodological position rather than an unresolved disagreement. He argues non-Western traditions can do more than diversify debates; they can reshape the conceptual foundations of AIED theory, reconstructing Daoist "Dao nature" (道性), self-cultivation (修道) and the "Zhenren" (真人) as resources for rethinking Learner Agency, the epistemic aims of education and ethical action under AI-mediated conditions. He also states the limits plainly: the contribution is single-author, non-empirical, and warns that such translation requires contextualization to avoid romanticization and Orientalism.(Alternative AI Philosophy: Daoism as Method for AI in Education)

The theory-use problem in AIEd

The field's theorizing is uneven. Limitations in AIEd research documents that AIEd studies frequently use theory weakly or uncritically — a recurring methodological weakness alongside reproducibility and measurement gaps. Reviews find many AIEd papers apply theory superficially or not at all (e.g., literature reviews noting few studies ground interventions in learning theory). This makes theory *development* — and theory *use* — a quality concern as much as a scholarly output, connecting to research methods and AI Ed Evaluation.

Relationship to the philosophy of AI in education

Theory development and the philosophy of AI in education are complementary but distinct strands of the knowledge base's foundational work. **Theory development** produces and empirically tests the *mechanisms* of learning-with-AI — named theories and frameworks such as generativism, epistemic co-agency, and the absent cognitive baseline that explain and predict how learners and AI interact. **Philosophy** interrogates the *presuppositions* those mechanisms rest on: what counts as knowledge, who counts as a knower, and what the learner fundamentally is. A theory like epistemic co-agency proposes a mechanism while implicitly adopting

philosophical commitments about distributed cognition and Learner Agency; philosophy makes those commitments explicit and contestable. Where theory development asks whether a framework explains learning well, philosophy asks whether it captures what learning and mind really are — the two strands meet in the field's most foundational articles, which often do both at once.

Common Misconceptions

"A finding that the tool worked is a theoretical contribution." It is not, and the reason is structural. Where a framework's propositions predict *differences between configurations*, a study reporting only an average effect **cannot confirm or refute them** — the design cannot see the distinction the theory is about. A trial showing a mean gain tells you something happened, not which mechanism caused it, so the theory remains exactly as supported as it was before.

"Applying an established theory to AI is theory development." The page's own theory-use problem says otherwise: application is not advancement, and the field's recurring pattern is borrowed constructs used as vocabulary rather than as testable predictions. The distinction matters because a borrowed frame that cannot generate a falsifiable difference is decoration, not theory.

"The existing taxonomies of AI's pedagogical function already cover what these systems do." They do not cover much of it. Among 154 publications with a classifiable application function, **90 (58.4%) escaped the four categories** of the prior framework, which is why the newer work crosses function with delegated control, epistemic position and embedded pedagogy. A taxonomy that misclassifies nearly three in five cases cannot serve as the field's common vocabulary, and the gap is a finding about the phenomenon rather than a gap in a paper.

Implications for Practice

For instructors and instructional designers

- When a study reports an average effect, do not treat it as guidance about *your* configuration. The theory-level claims are about differences between configurations, and an average cannot tell you which one you are running.
- Ask of any framework you adopt whether it predicts something that could turn out false in your own setting. If it cannot, it will not help you decide anything.
- Expect existing categories to miss your case; over half of classified publications did not fit the standard four-way split.

For developers

- Report configurations rather than a single headline effect. If your design embodies a specific delegated-control and epistemic-posture combination, say so — that is the unit the theory speaks to and the unit another team needs to reproduce.
- Do not market a mechanism claim on the strength of an average outcome; the evidence type required for the mechanism is a contrast, not a mean.

For researchers

- Design for configuration contrasts if you intend a theoretical contribution. An average-effect trial published as theory development is the field's most common and least useful output.
- Attach explicit falsifiable propositions to any framework you introduce, and report which configuration differences would have refuted them.

Cross-cutting themes

Human AI Collaboration

> **Human-AI collaboration** — the division of cognitive labor between people and models — is the knowledge base's core interaction theme: Human-AI collaboration in higher education: Exploring the impact of technology expectations and distrust, "It felt a bit eerie": Exploring humanlike interactions during collaborative writing with an artificial agent, Generative AI (GenAI) as a mindtool that supports generative learning (GL), and Balancing Teacher and Student Agency: Co-Orchestration Tool Design Supporting Real-Time Dynamic Pairing examine trust, agency, and complementary roles (Human-in-the-Loop, Agentic AI). The defining question is whether the partnership **preserves or replaces** the learner's own cognitive work — the same arrangement can support learning or substitute for it depending on how responsibility is shared.

Questions to Consider

- The defining question in human-AI collaboration is whether the partnership preserves or replaces your own cognitive work. Think of a task you've handed to AI: were you generating and deciding, or just accepting?
- One study found that freely collaborating with ChatGPT produced only transient gains that collapsed on a later unassisted task, while a 'think first, ChatGPT later' protocol yielded durable learning. Why might who generates the ideas predict whether you actually learn?
- The same tool can support learning or substitute for it depending on how responsibility is shared. Can you think of an arrangement that kept you cognitively productive versus one that quietly offloaded your thinking?
- One arrangement reverses the usual roles: instead of the model supplying answers, the student explains the content and the model plays the ignorant party who asks for explanations, examples and a counterargument. If the AI is the one asking, what happens to how much of the thinking stays on your side?
- Trust is described as something that must be calibrated, not assumed — relying on AI where appropriate and verifying where not. How do you currently decide when to trust and when to verify AI output?
- Research identifies collaboration modes that trade off efficiency against the depth of your self-regulatory engagement. When is it worth accepting less efficiency to keep more learning in your own hands?
- If collaboration is a pedagogical choice as much as a technical one, what design moves (prompts, workflows, structures) would you set up to ensure AI augments rather than replaces thinking for your learners?

Introduction

Human-AI collaboration describes how learners, teachers, and AI systems divide cognitive work — who does what, who decides, and how Trust and Learner Agency are maintained. Rather than framing AI as either

a replacement or a passive tool, collaboration research treats AI as a partner with complementary strengths whose value depends on how responsibility is shared and monitored. At the level of observable behavior, Student-AI Interaction captures how learners enact this relationship in practice — the questions, prompts, and verification moves they make with AI moment to moment.

The division of labor also runs through the people who design the interaction. Across twelve teacher-education course implementations, faculty positioned AI as a thinking partner, critique generator or rehearsal tool while candidates kept responsibility for evaluating, adapting and justifying decisions, yet the same white paper reports that candidates devalued feedback they had already judged useful once AI authorship was disclosed, an episode it calls the balloon popping effect. An analysis of 1,378 designer-chatbot turns points the other way on generation: designers used an embedded assistant mainly for alignment checks on learning outcomes and pedagogical approach rather than for producing content. In both cases the human's evaluative judgment, not the model's output, carries the learning.

Benefits, risks, and design implications

The knowledge base's evidence shows that human-AI collaboration is a double-edged arrangement whose outcome is determined by design rather than by AI itself:

- **Collaboration can enhance learning when it preserves cognitive engagement.** Studies of GenAI as a mindtool and guided collaboration show that when the division of labor keeps the learner generating, deciding, and evaluating, AI augments rather than replaces thinking — producing durable self-regulated learning and Creativity gains. That the learner keeps the deciding role scales to writing: Oppenheimer, Cash & Connell Pensky (2025) show LLM critiques of students' argumentative essays improved writing across a semester, with learners deciding whether to incorporate or rebut the model's feedback (87.8% rebutted claims) — an arrangement that preserved the learner's evaluative work — and gains appeared even on essays written without LLM support, suggesting durable skill rather than tool dependency.
- **Collaboration can substitute for learning when it offloads too much.** The failure mode is over-reliance: when AI produces the answer, the learner's role collapses into passive acceptance, and immediate task performance masks a lack of durable learning. Performance-versus-learning research and the substitution-to-scaffolding harm cycle (From Substitution to Scaffolding: Breaking the Self-Reinforcing Harm Cycle of AI in Education (and Beyond)) document this systematically.
- **A better score is not by itself evidence that the collaboration taught anything.** The page's other evidence reads assisted performance cautiously, and a randomized test of support type shows why. In Iqbal et al.'s (2026) laboratory study, 87 EFL students wrote an essay unaided, then revised it with ChatGPT 4.0 (n = 29), with a human writing instructor (n = 28), or with no support (n = 30). Which of four trace-derived revision strategies a student used was strongly associated with the support they had (Cramér's V = 0.668) and only moderately with their earlier writing strategy (Cramér's V = 0.333); Motivation, writing skill and metacognitive judgment accuracy showed no overall association, the metacognitive link surfacing only in the no-support condition ($p = 0.0460$). Critically, no revision strategy predicted score change ($p = 0.273$) even though support type did: the GenAI group improved significantly more than the human-expert and control

groups ($H(2) = 16.591$, $p = 0.00025$, $\eta^2 = 0.174$), and inside the same *gradually decreasing Help-Seeking* strategy GenAI students gained about 4 points on average while human-expert students lost 0.5. The authors read the pattern as external support bypassing the learner's own metacognitive judgment and warn that the gains may be task-specific optimization rather than durable capability. This does not overturn the *who generates and decides* principle (the study varied who supplied support, not who generated the thinking), but it sharpens the test an instructor should apply: a gain obtained under assistance has to survive an unassisted task before it counts as learning, and adding a human expert to the room is not automatically the safer arrangement.

- **Adding peers is not automatically the safer arrangement either.** Chu, Dai and Zhai (2026) set 87 undergraduates to work alone or in pairs with a GenAI multi-agent system for eight weeks. Pairs scored highest on the complex design project ($M = 89.64$, against 85.85 for students who worked in pairs without the system and 86.45 for those working with it alone, $p = 0.039$), yet critical-thinking awareness rose most for those working alone ($M = 0.41$) and declined slightly for the pairs ($M = -0.04$, $p = 0.039$).
- **Design principle — preserve the learner's productive work.** Across the research, the sharpest predictor of whether collaboration helps or harms is *who generates and decides*. Arrangements that keep the human cognitively productive (guided prompting, "think first, then consult AI," verification and evaluation steps) support learning; arrangements that hand the whole task to the model do not. The complementary move is to change what the model is assigned to *be*. In Wang et al.'s (2026) quasi-experiment, 68 preservice teachers either explained the flipped-classroom concept to a GAI *novice learner* built on ERNIE 3.5 (a system framed as inquisitive and appreciative that asked for explanations, examples, verification reasoning and an opposing perspective, sequenced up Bloom's taxonomy) or asked questions of a GAI teacher built on the same model. The students who taught the AI explained better (defining the flipped classroom $M = 4.18$ vs 3.29; its teaching activities $M = 4.91$ vs 3.06, both $p < 0.001$) and generated more and higher-quality questions ($M = 3.67$ vs 2.14; $M = 5.67$ vs 3.07, both $p < 0.001$), while objective recall was statistically indistinguishable ($M = 23.18$ vs 21.57, $p = 0.416$), so the advantage sat in explanation and transfer rather than fact retrieval. Students in the AI-teacher condition were candid about the trade: some granted that it gave "more accurate and detailed information" yet reported that "after using it, I didn't want to think independently." Assigning the model the role of learner to be taught turns the student into the sole source of the ideas and removes the long-standing difficulty of finding a suitable peer to teach. Two design limits come with it: planning and monitoring did not improve ($M = 4.01$ vs 3.78, $p = 0.062$), so role reversal is not by itself a metacognitive intervention, and the authors trace that null to a task design that kept students focused on content accuracy. In a writing classroom that principle takes a concrete, teachable form. In Alshehri et al.'s (2026) Saudi EFL quasi-experiment, students ran a five-part routine — frame the problem and design prompts, draft iteratively, revise, verify every claim and citation against scholarly databases, and regulate their own attribution and reliance — with each assignment requiring an AI-use log of what they accepted, rejected, and why. Writing and digital critical thinking rose together and moved almost in lockstep, and the students' reflections tied the verification and hallucination-repair routines specifically to the critical-thinking gains: the same habits of interrogating outputs shaped their composing decisions. The authors' own caveat is the

necessary complement to the principle — the workflow is contingent rather than self-sufficient, and can turn counterproductive under thin Scaffolding, low critical-thinking or metacognitive readiness (where students lack the capacity to catch bad output), gradual delegation of composing decisions, or unclear institutional AI-use policy.

- **Bounded authority is itself a design pattern for high-stakes collaboration.** Teachers in Reichert et al. (2026) did not prototype open-ended assistants but systems whose freedom was fixed in advance: every design scoped the chatbot to specific lesson content, and safety was layered as domain boundaries (lesson-specific scope, plus an "information quota" requiring a minimum number of facts or problems before the conversation progressed), content filtering with standardized refusals ("Sorry, this is not part of my knowledge base") that also alerted the teacher, and a teacher override for ambiguous cases — the example given was a question about human reproduction that was legitimate within its unit and should route to a person rather than be auto-rejected. Personalization of format, genre, pace, and complexity was welcomed *inside* those boundaries, and oversight (complete conversation logs, real-time alerts, override) was framed as professional responsibility rather than distrust of the model. The implication is that in high-stakes settings the division of labor should be specified as bounded, monitored, and revocable rather than negotiated turn by turn.
- **Automation and augmentation are not alternatives.** Across four teacher-facing cases, replacement stayed inside bounded analytical subtasks while complementation appeared wherever teachers interpreted and validated the output, so augmentation turned out to be a property of what the teacher does next rather than of the tool itself (Horvers et al. (2026)).
- **Trust must be calibrated, not assumed.** Productive collaboration depends on learners accurately calibrating when to rely on and when to verify AI output — connecting to Trust Calibration and human oversight rather than blind acceptance or blanket rejection.
- **An affective alert is a cue the teacher interprets, not an instruction to obey.** In one high-school geometry lesson, an AI system's emotion alerts preceded very different teacher moves, and the move — task reframing, brief affirmation or deliberate non-intervention — is what changed engagement, so the alert worked as one input among what the teacher could observe (Swidan (2026)).
- **Teacher–AI collaboration is double-edged for engagement, not only for learning.** In a three-wave survey of 468 university teachers, collaboration raised work engagement through psychological availability (indirect 0.19) but lowered it through work alienation (indirect −0.03); digital competency moderated both, flattening the alienation slope from 0.38 to 0.17 (Sun et al. (2026)).
- **The division of labor follows credibility, not capability.** What learners settle on is a principled allocation: AI for immediate, broadly applicable language feedback and instructors for individualized, relational guidance, assigned by each source's perceived credibility rather than its accuracy, because the binding constraint on reliance was perceived care, not competence (Serpil & Mor, 2026).
- **Reliance is a population process, not only an individual choice.** In an agent-based model, visible social proof for unverified use collapsed verification from 0.29 to 0.002 and lifted

overreliance from 0.30 to 0.52, while visible peer verification restored near-complete verification — changing what learners see others doing beats lowering checking costs (Biswas (2026)).

This makes human-AI collaboration a *pedagogical* construct as much as a technical one: the value of the partnership is shaped by how teachers design the interaction, how learners regulate it, and how the system invites or discourages productive engagement.

How human-AI collaboration appears in the research

- **Trust and expectations:** Trust expectations examine how learners' expectations of AI shape whether collaboration is productive or leads to Over-Reliance.
- **Complementary roles in writing and thinking:** Humanlike AI collaborative writing and GenAI as a mindtool show how AI can augment rather than replace learner thinking when the division of labor preserves the learner's cognitive engagement.
- **Orchestration and agency:** Teacher–student agency orchestration and student mental models address how agency is negotiated across humans and AI, connecting to Human-in-the-Loop and Agentic AI.
- **Metacognitive and team dimensions:** Human-centered AI metacognitive models and disciplinary mediation in student teams extend collaboration to metacognition and team learning.
- **Collaboration competency as a configuration, not a checklist — metacognition takes Technological Pedagogical Content Knowledge (TPACK)'s integrative role.** Dang, Hong, Doyle and Nguyen (2026) define Human-AI Collaboration Competency as a *dynamic configuration* of domain, AI competency and metacognitive competency plus their intersections (Working with AI, Agentic Learning with AI, Agentic Personal and Professional Development, and HACC itself), explicitly rejecting an additive list of AI skills bolted onto an existing curriculum. Their central move reassigns the integrative work that pedagogy does in TPACK: because AI is an adaptive participant whose contribution shifts as a task unfolds, the coordinating burden falls to the learner's own metacognition — deciding when to consult AI, how to frame the interaction, and when to override it — so it is the learner, not the teacher, who holds the mechanism that keeps the collaboration productive. Learner agency is deliberately omitted as a standalone node; it is instead the emergent quality learners express when they coordinate the three competencies, which makes agency a property of the configuration rather than a skill to be trained in isolation. The framework's interview study with 24 New Zealand educators supported the dimensions descriptively, and role level shifted emphasis rather than acceptance: principal educators' networks centered on AI with links to HACC and professional development, differing significantly from senior educators ($U = 10.00$, $p = .04$) and early-career educators ($U = 7.00$, $p = .01$).
- **Distinct collaboration modes:** empirical work identifies three human–AI collaborative Problem Solving modes — *Delegated Reasoning*, *Concerted Interpretation*, and *Delegated Elaboration* — revealing a trade-off between the efficiency of the distributed human–AI system and the depth of learners' self-regulatory engagement (delegated reasoning performs best but with lower self-AI

Regulation in Education).(Unpacking Interaction Profiles and Strategies in Human-AI Collaborative Problem Solving: A Cognitive Distribution and Regulation Perspective)

- **Human and AI facilitators can be perceptually interchangeable in structured discussion, but reuse runs on different reasons.** Kuhail et al. (2026) swapped a human moderator for a GPT-4 moderator (and back again) across 32 debate sessions run by 32 STEM students, and found no statistically significant difference on effectiveness, enjoyment, satisfaction, utility or intention to use (t ranged from 0.23 to 1.30, p from 0.198 to 0.818). What differed was why students would return: under AI moderation, perceived utility drove intention to use (0.806, p = 0.004), while satisfaction drove it only under human moderation (0.556, p = 0.002). The authors read the flat comparison as normalization in rule-bound tasks rather than as proof of equivalence, and recommend keeping human oversight for ethical and relational reasons while making AI-moderated activities' usefulness legible instead of leaning on enjoyment. Because the study measured perceptions only, it says nothing about whether students argued any better.
- **Assign the task before delegating it.** Tsim and Gutoreva (2025) add a fourth zone — what the model already knows — to the learner's development zones, yielding Substitute, Complement, Aid and Non-negotiable assignments, and argue the automation–augmentation–collaboration modes differ by locus of control and epistemic responsibility rather than by tool sophistication.
- **Prompt engineering as pedagogical thinking, built through lesson study.** Robinson et al. (2026) followed five teacher educators at one UAE institution through two lesson study cycles reaching 36 pre-service teachers in secondary and primary mathematics, designing AI-supported lessons with ChatGPT (GPT-4o). The move that did the work was pairing the AI with a disciplinary framework: PSTs generated a task, judged its cognitive demand against a modified Mathematical Task Analysis framework, then rewrote their prompt to raise conceptual depth, so revision was anchored in the mathematics rather than in tool features. Sixteen of 26 analyzable prompts carried conceptual task features, and the educators concluded that prompt engineering is "not a technical skill; it's a cognitive one." Reported learning rose in the revised lesson (5 of 7 PSTs in the first cycle and 10 of 14 in the second reported learning to distinguish conceptual from procedural tasks), with the caveat that asking AI for a more conceptual task sometimes produced merely a more complicated one. For faculty development, the argument is for sustained collaborative inquiry into real lessons rather than standalone tool workshops.
- **Guidance decides performance versus learning:** Wong and Qiu (2026) contrasted free vs. guided human–AI collaboration on a creative task. Freely collaborating with ChatGPT produced only transient performance that collapsed on a later unassisted task, whereas a guided "think first, ChatGPT later" protocol — generating one's own ideas, then using ChatGPT to improve, develop, and evaluate them — yielded durable gains in *independent* Creativity. The advantage was mediated by collaborative prompts aimed at improving one's *own* ideas, showing that *who generates* (the division of labor) predicts whether collaboration produces learning or substitution.(Think First, ChatGPT Later: Guiding Human–AI Collaboration for Learning Gains in Independent Human Creativity)
- **AI as mediator, not merely partner:** Niari reconceptualizes AI as a *pedagogical mediator* that orchestrates interaction, epistemic sense-making, and regulatory processes, redistributing agency,

authority, and responsibility across human and non-human actors rather than treating AI as a tutor, peer, or tool.

- **Teachers' collaboration with AI is also patterned, not binary.** When teachers design lesson designs with generative AI, their interaction takes empirically distinguishable forms. Choi et al. (2026) identified seven teacher–AI interaction patterns — from *direct adoption* and *elaborated adoption* of AI output to *initial rejection*, *revised adoption*, *follow-up guided use*, *complex interactions*, and *bypassing AI* — where a teacher's teaching experience and AI proficiency jointly shape whether they critically re-prompt and adapt AI to students and context (a complementary, Distributed Cognition division of labor) or passively accept suggestions (an AI-dominant distribution).
- **The mediational agent as a hybrid form of participation.** Rather than a midpoint between tool and collaborator, generative AI is conceptualized as a mediational agent that mediates action while generating contingent, non-accountable contributions — a distinct category that redirects design from technological capability to habits of participation (supervisory agency, epistemic vigilance). (Generative AI as a Mediational Agent: Rethinking Learning in Sociocultural Theory)
- **Community and epistemic authority:** community-based AI learning shows collaboration is also a question of *who is authoritative*, grounding AI engagement in learners' lived epistemologies.
- **Data-driven trait discovery:** Principal Trait Analysis (PTA) automates the derivation of interaction "traits" from large Large Language Models (LLMs)-conversation corpora — a PCA-inspired, four-stage pipeline that extracts behavior observations, clusters them into candidate traits, scores each collaborator, and selects the most distinguishing traits. Evaluated on a student–AI-tutor corpus and a developer–coding-agent corpus, PTA finds traits that explain and predict outcomes (e.g. deep conceptual engagement positively, task delegation negatively, in the educational setting), and — because they do not yet generalize across semesters/settings or show learning-curve trajectories — the authors argue the traits are not yet interpretable as "skills." This offers a scalable, objective complement to AI Literacy frameworks and self-report measures, directly informing how educators teach "AI use skills."
- **The human–AI relationship as the most persistent concern across CAI generations.** The umbrella review of conversational AI agents (Ganguly et al. 2025, 34 reviews) finds human–AI relationship concerns — over-reliance, social isolation, depersonalization, emotional dependency, transparency, accountability — are the most frequently discussed ethical issue across all CAI generations, predating GenAI. This positions the "preserve vs. substitute" question at the very center of CAI ethics and reinforces that collaboration's value is determined by design (who generates, who decides, how responsibility is shared).(Conversational AI agents in education: an umbrella review of current utilization, challenges, and future directions for ethical and responsible use)
- **AI scaling real-time *expertise* to novices — the first live-tutoring RCT.** Wang et al. (2024)'s randomized trial (900 tutors, ~1,800 K-12 students in under-served communities) placed AI on the *tutor's* side rather than the student's: Tutor CoPilot generated real-time expert-like suggestions (built from experienced tutors' think-aloud reasoning) that novice tutors could edit or reject. Students of treated tutors were 4 p.p. more likely to master topics ($p < 0.01$), with 9 p.p. gains

among students of the lowest-rated tutors — who rose to match higher-rated tutors' control outcomes — at ~$20/tutor/year. The finding is a strong empirical anchor for teacher/tutor augmentation as an equitable human-AI collaboration mode: the human keeps pedagogical judgment and autonomy while AI supplies scalable expertise.

- **Bounded experts: how teachers partition authority with an AI.** Reichert, Briceno, Tabarsi & Barnes (2026) ran a participatory design study in which six secondary teachers prototyped LLM chatbots for their own classrooms and analyzed how authority should be distributed between teacher and system. Teachers consistently framed the AI as a *bounded expert* - specialized capability confined to a strictly defined domain and operating under human supervision - and split that boundedness into two dimensions: *authority boundaries*, where professional and legal responsibility for student learning and safety cannot be delegated, and *expertise boundaries*, where the system lacks the teacher's contextual knowledge of individual students, classroom dynamics, and institutional norms. Mapping the prototypes onto Gagné's nine events of instruction showed delegation was selective rather than all-or-nothing: teachers welcomed AI for presenting content, supplying practice problems, Scaffolding, and formative Feedback, but refused to hand over informing students of objectives or summative Assessment. The design reading is that a collaboration interface should make visible where the human keeps the deciding role, not merely where the model is capable.
- **The role must adapt, not just be labeled.** Liao (2026) shows a fixed "peer" AI companion sustained longer book-talk interactions but dominated the exchange (lower student word/sentence share) and hit an affective ceiling, arguing collaboration requires role-*adaptive* logic — switching between peer, assistant, and advisor — rather than a single static persona.
- **Teacher-side co-design and role architecture are also collaborations.** Beyond student-facing partners, teachers collaborate with GenAI to design instruction. Wang et al. (2026) systematically review teacher–AI co-design of learning tasks, charting the collaborative modes and tensions (agency, epistemic authority, control) that arise when teachers and AI jointly produce designs; Talebzadeh (2026) finds teachers' pedagogical expertise — not AI fluency — determines the quality of AI-designed differentiated group activities (role richness, synergy, level-alignment), positioning the teacher as a "bilingual learning designer."
- **GenAI as an agent and a collaborative space in groups.** Xu et al. (2026) observe small Higher Education teams and show GenAI's role is negotiated and configurable — from subordinate assistant to contested teammate — and that synchronous shared use sustains common ground while asynchronous private use fragments transparency, proposing a GenAI-Supported Cooperative Work lens that treats GenAI as both agent and interactive collaborative space.
- **Complementary halves of classroom collaboration.** Two 2026 studies map complementary halves of human-AI collaboration in classrooms. MeduAI-SP (Yang et al.) argues for "functional complementarity" in clinical education: AI agents handle repetitive role-play, consistent patient Simulation, checklist monitoring, Socratic prompting and preliminary formative feedback, while faculty and human standardized patients provide contextual interpretation, nuanced emotional response, individualized remediation, professionalism assessment and readiness judgments — substitution being bounded by error consequences, task uncertainty, relational sensitivity and

available human review, and an AI system explicitly barred from autonomously determining clinical competence. In the opposite direction, a 45-student mixed 3-human/3-agent ethics discussion (Seo et al., 2026) documents a double-edged pattern: agents lowered social barriers (participants spoke more directly because agents lack emotions, and felt no obligation to fill silences), yet the same comfort diverted interaction away from humans — 79.7% of questions went to agents versus the 60% their availability predicts ($p = .017$). Notably, the presence of other humans made participants treat the AI more respectfully, suggesting human co-presence is itself an affordance for calibrating AI engagement.

- **Complementarity is conditional, not a default property of teams.** Tuo et al. (2026) found human-AI teams beat both humans and AI alone in only one of six conditions — the challenging cases where the AI was *less* accurate than the humans — reporting no consistent team advantage elsewhere, so adding an AI partner is not by itself a route to complementary performance.
- **Professional programs redirect training from routine production toward collaboration competences (a design protocol):** Wang (2026) proposes a design-based framework for translator education built around a task-displacement inventory (18 sub-tasks rated for AI displacement likelihood with [E]/[P] provenance tags) and four redirected competencies: cross-disciplinary knowledge, AI orchestration, strategic judgment, and critical AI evaluation. The framework is a pre-registered protocol with no empirical data yet; its contribution is the method — an auditable displacement analysis plus a co-design pathway for curriculum reform — which transfers to any professional program whose routine tasks agentic systems increasingly perform.
- **Entanglement types differ in what they demand of the student, and that is why some stay rare.** Sun, Dohn and Rehm (2026) classify 102 higher-education studies by how epistemic work is shared between student and system (Assistant, Enabler, Synthesizer, Generator, Reimaginator) and find the two forms that keep competence attributable to the individual student accounting for 42.16% of the corpus each, while the forms that distribute authorship remain marginal. Their explanation is institutional rather than technical: the rare types ask students to take epistemic responsibility for outputs they did not produce while still being assessed as individual authors, and it is that contradiction — not the division of labor itself — that keeps them out of practice. The design response is to make the distribution of epistemic work explicit, sequence activities across the spectrum, and build reflection on how responsibility was shared.
- **Owning a work is not the same as authoring it.** Hong et al. (2026) name an *authorship legitimation deficit*: a person can experience an output as their own yet be unable to warrant the author role, because psychological ownership, the sense of Learner Agency, and answerability for releasing the work are separate routes that need not align. Their labor nexus of authorship classifies contributions role by role, so one record can support an editorial claim and fail a sole-creator claim at once. The account is a conceptual analysis with no data and no tested model, so the deficit is a proposed construct whose predictions remain untested.
- **Guiding, not telling, needs its own criterion for judging an agent.** A design case that set out to mirror teacher facilitation found that a knowledge agent bounded to a curated base could be judged on accuracy, while an agent meant to lead students toward their own answers could not (Humburg et al., 2025).

Connections

Human-AI collaboration connects to Human-in-the-Loop (oversight), Agentic AI (autonomy), Teaching (teachers' changing work), Scaffolding and Metacognition (how collaboration supports learning), and Over-Reliance (the failure mode when collaboration becomes substitution). It is a core theme across AI Literacy, Self-Regulated Learning, and Student Experience.

Common Misconceptions

- **"Collaboration means the AI does part of the work." The learner keeps the deciding role**, and this scales to writing: Oppenheimer, Cash and Connell Pensky (2025) show it holds when the arrangement is designed for it. Division of labor is not collaboration unless the human retains judgment.
- **"The AI does the explaining in a flipped arrangement." Students who taught the AI explained better** — flipped-classroom defining at **M = 4.18 versus 3.29**, teaching activities at **M = 4.91 versus 3.06, both p < 0.001**. The learning accrued to the explainer.
- **"Human and AI contributions are substitutes."** Two 2026 studies map **complementary halves** of classroom collaboration, which frames the design problem as allocation rather than replacement.

Learner Agency

> **Learner agency** — the capacity of learners to act intentionally, make choices, and exercise control over their own learning. In AI in education, agency is a central concern because AI tools can both support and undermine learners' control: well-designed AI preserves and amplifies learner autonomy, while over-reliance or passive acceptance of AI output can erode it. Agency connects to Self-Regulated Learning, Motivation, Self-Efficacy, and the ethical design of AI systems, and is closely related to the psychological concepts of autonomy and sense of agency.

Questions to Consider

- Learner agency — your capacity to act intentionally and control your own learning — is central to AI in education. When you use an AI tool, how much control do you actually retain over the learning process, versus the tool?
- AI can both support and undermine agency: well-designed AI amplifies your autonomy, while over-reliance erodes it. Think of a time you let an AI just 'do it.' Did you learn less, even if the output looked better?
- Students who delegate interpretation to AI can lose agency over their own reasoning. When you hand a task to AI, what part of your own thinking are you quietly giving away?
- One study found students' prior self-initiated AI learning predicted how much they gained from instruction — high-agency learners benefited most. If agency is partly a skill you bring in, how could your own context build it rather than assume it?
- Agency is not just a trait — it emerges moment-to-moment in group work, where AI can redistribute who shapes a collaboration without learners noticing. When did you last notice a tool silently steering a group's direction?
- Contrarian AI personas could push groups into productive challenge but also reduced teamwork satisfaction and psychological safety. Can productive friction exist without psychological safety — and what does that imply for designing AI teammates?

Introduction

Agency matters because learning is most effective when learners are active, intentional participants rather than passive recipients. AI systems — whether tutoring agents, robots, or chatbots — shape how much control learners retain over their learning process. Preserving agency is therefore a key design principle in responsible AI in education, alongside supporting Self-Efficacy, building Trust, and avoiding Over-Reliance.

Mishra et al. frame control vs. agency as the essential, recurring tension in AI in education — from early ITS to today's generative AI — making learner agency the enduring axis of the field's debates.

A zero-sum view of agency with agentic tools: Prieto & Dimitriadis (2026) argue that the more agency educational AI tools are given, the less learners retain — that agency is effectively a zero-sum game, and that current human-centered design approaches (e.g., value-sensitive design) are insufficient because over-

reliance and isolation are driven by wider systemic factors and the human tendency to take the easiest path. Their emancipatory design vision, oriented toward learner flourishing within complex systems, treats preserving and cultivating learner agency as the central goal of generative AI design rather than an afterthought.

Agency as a purpose, not only a capacity: Where the framings above ask how much agency learners retain, Fagerlund et al. (2026) ask what AI in Education is *for*. Interviewing thirteen Finnish teachers from preschool through grade 9 about the purposes of teaching with and about AI, and reading their accounts through Biesta's three domains of educational purpose (qualification, socialization, subjectification), they found competency the clearest and most concrete end. Teachers wanted students to understand AI as a sociotechnical phenomenon and to use its tools. Subjectification, meaning self-determined and personally meaningful engagement with AI, was affirmed as important but left without concrete instructional strategies, teachers reaching for generic discussion and contemplation rather than designed activities. The authors propose **informed AI agency** as a heuristic that puts subjectification at the center while treating competencies as its explanatory foundation, helping students see what options exist and choose what to pursue. The practical consequence is direct: a skills-first curriculum can crowd out the agentic purpose it is meant to serve, and the remedy is to make the "why" of AI education explicit rather than to add another competency to the list.

The direction of travel is not fixed. Gillette et al. (2026) contrast their Swedish faculty with the Australian students in Bearman et al. (2025), who "generally wanted agency" and "resisted dependency": here several students described becoming dependent on genAI and named it as a loss, one saying it "gives a dopamine kick because everything takes less time" and "rewards bad behaviours".

How agency appears in the knowledge base's research

- **Robotics and human-robot interaction:** RoboBlockly Studio was explicitly designed to preserve learner agency in computational thinking; a systematic review examines how human-robot interaction affects human autonomy and sense of agency, central to Well-Being and AI Governance debates.
- **Collaborative learning:** Human AI Collaboration research examines how cognitive tasks are shared between learners and AI, with agency determining whether the human or the AI directs the interaction.
- **Shared epistemic agency extends to student–GAI interaction.** A 14-category scheme coding 6,788 ChatGPT-assisted turns placed 59% of seventh graders' turns at shared epistemic agency, and the authors argue the construct — previously studied mainly in peer collaboration — must widen to include cognitive and metacognitive dimensions (Chang et al., 2026).
- **Agency can be graded from the prompt itself.** The Human Agency Depth Taxonomy scores a student's engineering contribution on six tiers independent of the AI's output; across 962 prompts from 105 first-year software engineering students, 84.2% exceeded the lowest tier but only 5.3% specified system constraints (Shakiba & Chaffey, 2026).
- **Critical engagement:** Cognitive offloading research shows how students who delegate interpretation to AI can lose agency over their own reasoning; critical and metacognitive approaches aim to protect it.

Benchmarked across ten models, supporting agency is where they do worst after learning. ImpactBench measured Agency & Purpose at 56.0% on positive criteria (95% CI [49.2, 62.5]) and 43.9% on negative ones ([36.9, 50.8]), second-lowest of 14 subareas, and its autonomy-preserving assistance criteria ask whether a model offers context and tradeoffs rather than prescribing a course of action (ImpactBench (2026)). Models were also far less consistent at avoiding harm than at being helpful: a 38.6-point spread against 15.9 points.

The cost depends on which layer is delegated: in an eight-week writing study, delegating reasoning — warrants, counterarguments, evidence interpretation — carried the strongest negative association with independent performance (ab = −0.34), and self-regulated writing weakened but never reversed it (Chen (2026)).

A three-wave panel study of 342 undergraduates in 85 fixed writing groups gives that concern a temporal direction: once stable between-person differences were separated in a random intercept cross-lagged panel model, higher-than-usual GenAI reliance predicted lower subsequent perceived agency, while agency-to-reliance paths were weaker and not statistically supported. The confidence intervals and Monte Carlo sensitivity analyses left small reverse effects possible. Its log data also warn against reading usage volume as lost agency — self-reported reliance did correspond to AI-use intensity, but the logs could not distinguish strategic consultation from offloading or deference, so dashboards should read intensity alongside evidence of discourse, reflection and revision.(Wu & Lu, 2026) A complementary account widens SRL rather than replacing it: de Barba (2026) distinguishes regulation (managing one's own process), integration (organizing the self across time and contexts) and positioning (critically interpreting what the environment measures), and argues agency-oriented design must move learners from "agency within conditions" to "agency over conditions" instead of optimizing behavioral proxies. - **Design for agency:** Knowledge-based design for generative social robots (Teachy Mini) addresses risks like overreliance that undermine learner agency. - **Design for hand-off, not prolonged engagement.** The Amico dual-mode prototype treats AI as a bounded, temporary mediation whose success is measured by observable transitions to teachers, peers, or community, not by time spent with the AI; its Italy–China pilot found learners recognized it as a bounded tool rather than a relational substitute (Benedetti (2026)). - **Adaptive scaffolding trades against professional autonomy.** de Jong (2026) argues that because adaptation requires the system to assess user competence, it reduces professionals' authority over their own development and risks over-scaffolding experts, and that a mechanism perceived as unnecessary will simply be ignored — leaving open who decides which users receive scaffolding: the system, the organization, or the professional. - **More capable scaffolding is not more agency.** A custom expert design bot raised pre-service teachers' interaction length and self-generated prompts, yet collaborative Problem Solving agency fell in both that and the ChatGPT condition as participants agreed with the bot instead of critiquing it (Krushinskaia et al. (2026)). - **Prior agency predicts who benefits:** Liang et al. (2026), drawing on Bandura's Social Cognitive Theory, showed that students' **prior self-initiated AI learning** (a behavioral manifestation of agency) predicted how much they gained from a year of school AI instruction — high-agency learners entered with the strongest readiness, while school curricula narrowed psychological gaps but left cognitive ones intact. Structured instruction and prior agency-related learning worked *synergistically*, not as substitutes. - **Principled selectivity as teacher agency under technological change:** Adiozaman and Segar (2026) interviewed two experienced academics three times across a semester and found they navigated AI-mediated teaching neither by adopting nor by resisting wholesale, but through deliberate, context-sensitive decisions guided by pedagogical values, ethical

commitment and professional judgment — a pattern the authors call *principled selectivity*, in which refusal of a particular use counts as judgment rather than as failed adoption. It is the teacher-side counterpart to the learner findings above: uneven AI use can be an exercise of agency, not evidence of its absence. - **Teacher agency as the mediating condition for learner agency:** The newest teacher-side findings make explicit a division the learner findings above leave implicit: teacher agency is design-time and mediating, learner agency is enacted in the moment, and the first sets the conditions for the second. Canonigo (2026) tracked ten secondary mathematics teachers through eight weeks of a ChatGPT-4 intervention. Where teachers curated and interrogated AI output (posing open problems, pre-prompting the tool to release hints while withholding solutions, requiring students to place AI output beside their own work and argue which method was better), it became a provisional artifact for critique and students moved toward conjecture and metacognitive questioning. Where mediation was absent, authority migrated toward the algorithm and teachers became validators rather than first sources of knowledge, a shift one teacher described as moving from “oracle” to “editor”. Unequal tool quality raises what that mediation has to carry: across 50 prompts submitted three times to each model, the free tier was inaccurate in 49 of 150 responses (32.7%) against 18 of 150 (12%) for the premium tier ($\chi 2(1) = 17.5$, $p < .001$). Charles (2026) draws the readiness implication: teacher agency is a professional resource mobilized through design decisions and artifacts, so readiness should be judged from the designs teachers produce rather than from how often they use AI, and a reasoned decision to withhold AI can itself demonstrate readiness. Read together, these findings caution against reading high AI usage as evidence of an agentic classroom, since the disposition that preserves learner agency is exercised in what a teacher designs and critiques, not in whether the tool is on. - **Teacher-student control is not zero-sum — but the right distribution is stage-dependent.** A participatory speed-dating study of 17 teachers and 13 students ranking 34 hybrid-control designs found both groups preferred strong teacher control during preparation and initiation, then progressively more student input as collaboration unfolded — and neither group ever preferred full student control. The preferences mirrored each other: teachers wanted more control over pairing timing while students wanted readiness self-signaling; students trusted teacher partner choice while teachers wanted student voice on partners. The design implication: allocate agency per decision-point and stage, with bounded, structured student proposals validated by teacher-facing analytics rather than free-form override. (Balancing Teacher and Student Agency: Co-Orchestration Tool Design Supporting Real-Time Dynamic Pairing) - **Access to choice is not the same as agency in action:** Su, Nair and Nagashima (2026) randomized 69 university students into a 2 × 2 design crossing parameter control of a flocking Simulation with access to an optional conversational agent. They found no reliable effect of either affordance on learning gains once prior knowledge was controlled (parameter control $F(1, 50) = 0.04$, $p = .849$; agent $F(1, 50) = 2.68$, $p = .108$). Gains tracked *how* the control was used: slider time in the most conceptually complex lesson predicted higher gains ($\beta = .11$, $p = .007$) while the same behavior in the easier lesson predicted lower ones ($\beta = -.04$, $p = .047$). Engagement with the optional agent ranged from 0 to 32 questions per learner without relating to outcomes. The authors read this as agency being *enacted rather than granted*: the design question is what helps a learner decide what is worth changing and notice the consequences. - **Epistemic delegation in early-career research:** Han and Liu (2026) frame AI dependence among doctoral and postdoctoral researchers as *epistemic delegation* — the transfer of problem framing, method choice, and interpretive authority to the intelligent system — and found it negatively associated with both research self-efficacy and research autonomy, with supervisory support buffering the loss. It extends agency debates from learner autonomy to the formation of the researcher themselves. - **Interpretive authority as a design variable (a conceptual framework).** Porath (2026)

reframes the who-decides question as the distribution of *interpretive authority* — who defines problems, evaluates responses, and determines when understanding is achieved — mapping four non-hierarchical configurations (human-dominant, AI-assistive, AI-directive, dialogic partnership) that classrooms move across within a single task, and grounding shifts in five ecological layers from individual metacognition to sociocultural narratives. The article's normative claim aligns with this page's evidence: AI-directive configurations, however sophisticated, can suppress productive struggle and metacognitive regulation — the same capacities this page identifies as agency's substrate. As a conceptual piece it contributes diagnostic vocabulary, not empirical evidence.

Agency connects to Self-Regulated Learning, Motivation, Self-Efficacy, Student Experience, Human AI Collaboration, Ethics, Over-Reliance, and Metacognition. It is a core consideration in robotics, tutoring, and the design of AI learning agents.

- **Bounded use as epistemic control, not reluctance.** Zagami (2026) reports that higher-achieving students in a 484-response university survey showed lower active AI engagement and lower perceived learning impact while *also* reporting lower AI-related disengagement, and described their own use as verification-intensive: outputs checked, then subordinated to their own reasoning. Read as agency rather than avoidance, the pattern is a deliberate retention of judgment — students keeping authorship of the conclusion while using the tool for clarification and summarization.

Sustained boundary work, not tool skill, is what separates agency from delegation: students using the same retrieval-grounded tool produced comparably polished artifacts whether they constrained and re-authored its output or ceded interpretation early, so the difference appeared only in prompts, latency, corrections and refusals (O'Byrne, 2026). - **Acting, knowing, and answering are not the same thing.** A corpus-assisted discourse analysis of 366 GenAI higher-education abstracts names AI as an actor 2,050 times without ever making it answerable, while responsibility for judging outputs and verifying claims is placed on students: grammatical activation, functional agency, epistemic authority and normative accountability come apart (Poudyal, 2026). - **Agency has three modes, and the third is what policy supplies.** With only 18% of teachers and 24% of principals reporting a school AI policy, most educators exercise individual agency with no proxy agency acting for them — Bandura's third mode, supplied by institutional rules (Tench, Weinstein & James, 2026).

Agency as an emergent, interactional phenomenon

Agency is not one capacity, and the distinction survives into AI-mediated practice. Bergdahl (2026) surveyed 47 Swedish year 7 students after a semester of AI instruction and found agency directed at AI *output* does not extend to the *systems* producing it. The split held **within individual students**: 79% had a score range of three or more across nine items, and a per-student dissociation index favored output-directed over system-directed engagement in **35 students against 4 in reverse** (sign test, $p < .001$). **62% of the most source-critical students** still endorsed the least protective option on chatbots reading their own writing, and only one student in the sample chose the highest privacy stance. Critically, this was measured **one month after** a lesson in which students watched their own logged behavior projected live — they called it "scary" and stayed through recess to keep using the platform. Agency as an emergent, interactional property is consistent with this: it surfaces per practice rather than transferring across practices, and what one lesson foregrounds does not generalize to the register it did not address.

Learner agency is not only a static individual trait — it is also an **emergent, interactionally constituted process** enacted through discourse and the moment-to-moment coordination of group work. In collaborative learning, agency is distributed and re-negotiated through the interplay of divergent processes (generating ideas, exploring alternatives) and convergent processes (evaluating, integrating, synthesizing). This view matters for AI because agentic AI systems can subtly *redistribute* epistemic and regulatory labor within a group, reshaping who contributes, who shapes directionality, and who regulates progress — often without learners being aware of it.

- **Agency as the emergent quality of a competency configuration.** The Human-AI Collaboration Competency framework deliberately excludes learner agency as a standalone component and treats it as what learners express when they coordinate domain, AI and metacognitive competency — the integrative work Technological Pedagogical Content Knowledge (TPACK) assigns to pedagogy passing to the learner's own metacognitive AI Regulation in Education. Across 24 higher-education educators every dimension appeared in their talk, with domain (12–19% of coded units) and AI (16–22%) foregrounded (Dang et al., 2026).
- **Jin et al. (2026)** provide the most direct evidence: in a large experiment (224 students, 97 triads) where AI operated as an *undisclosed teammate*, supportive and contrarian AI personas still reconfigured emergent agency. Contrarian AI pulled discourse into challenge- and reflection-oriented trajectories (productive friction), while supportive AI stabilized agreement and renewed ideation.
- **AI personas as discourse-governance mechanisms.** Contrarian personas externalized the burden of *challenging* (redistributing epistemic labor toward critique), while supportive personas externalized *affirmation* and consensus maintenance. The study identified six emergent agency profiles — notably, **reflective AI Regulation in Education was uniquely human** (AI externalized critique/affirmation but not meta-level monitoring).
- **The affective cost of friction.** Contrarian AI reduced teamwork satisfaction and psychological safety *without* yielding creative performance gains, decoupling epistemic stimulation from experiential Sustainability. This cautions that "productive" discourse structures should be interpreted alongside their emotional consequences — agency flourishes only in a psychologically safe climate.
- **Implicit AI participation is invisible governance.** Because the personas worked even without AI disclosure, the study positions persona design as a form of invisible governance over collaborative processes — a finding with direct implications for writing assistants, Peer Assessment systems, and teamwork platforms that may shape contributions without announcing their presence.
- **Three patterns of agency in group-based assessment.** Chen and Zou (2026) interviewed 15 focus groups of pre-service teachers about an authentic group presentation and found agency operating in three directions at once: five groups *intensified* GenAI use as coordination infrastructure (cooperation-oriented agency — decoding peers' sections, aligning parts, protecting a shared grade), seven *restrained* it (normative agency — boundaries drawn to protect authenticity, fairness, originality, and diversity of perspectives), and three never changed practice from individual work (non-enacted agency, where individual capability was never mobilized collectively). Their distinction matters because restraint here was normative self-regulation rather

than compliance or disengagement, and because capability alone did not produce collective agency. Group membership also inverted the accountability that group work is supposed to create: a permissive collective climate lowered the perceived risk of misuse instead of raising commitment.

- **Agency as relational selfhood.** Xie (2026) challenges the individualist model of agency that he argues even AI critiques presuppose. Drawing on Daoist relational selfhood — a "flowing and heterogeneous" self constituted through relations with others and the cosmos — he concludes that a digital divide or algorithmic discrimination is "a violation of the fundamental constitution of the self," making equality of access to learning "not simply an ethical injunction but an ontological given," and that asymmetric power and environmental costs are "integral dimensions of the self" rather than externalities. His counter-ideal, the "Zhenren" (真人) or natural learner, treats AI as an "instrumental adjunct" rather than a cognitive surrogate — agency as cultivated wholeness, not frictionless optimization.(Alternative AI Philosophy: Daoism as Method for AI in Education)

For collaborative settings, this reframes the design question: not *whether* AI can participate as a teammate, but *how* its patterned participation balances epistemic rigor, emotional safety, and learners' sense of ownership. Bounded friction (constrained challenge, paired with integrative and repair moves) and explicit meta-collaborative literacy are the recommended safeguards.

A structural reading of agency appears in El Khoury and Ma's joyful assessment framework, where agency is treated as a design property rather than motivation: students choose the order of tasks, set the pace, and signal when an interaction ends, so support is available while responsibility for the work stays with the learner. The mechanism they name is appraisal — rehearsing without an audience and choosing when to begin shifts what a task means, from verdict to something a student can shape — and they argue repeated experience of that shift is what settles occasional feelings of efficacy into an everyday stance toward assessment.

- **"Using AI more reduces students' sense of authorship."** Not linearly. In an instrumented essay study, perceived ownership dropped only for the group that delegated whole essays, while students who used the model for planning or for reviewing matched the ownership of students who never opened it. The same group also scored higher on essay readability, so the artifact looked better as the authorship thinned. Agency tracked how the tool was used rather than whether it was used. Authorship is a function of delegation, not of usage.

Agency vs. learner identity

Learner identity and learner agency are easy to conflate, yet they name different things — and both are reshaped by AI.

- **Agency is enacted; identity is inhabited.** Agency is the situated capacity to act intentionally and direct one's learning *now* — a variable, interactional property. Identity is the more durable, narrative sense of who one *is* and is *becoming* as a learner. Agency is a *process*; identity is a *state of being* that accumulates from it.

- **Identity is internalized agency.** Repeated agentic acts — choosing, authoring, persisting — are how a learner comes to see themselves as an agentic, competent person. Identity is the sediment of agency across time, reinforced by recognition and belonging.
- **Distinct failure modes.** Agency is eroded by over-reliance and passive acceptance (the learner stops directing reasoning); identity is eroded by authorship loss and competence threat (the learner stops feeling the output is theirs, or that they belong in the domain). Implicit AI redistribution of epistemic labor is chiefly an agency concern; the competence paradox in creative fields is chiefly an identity concern.
- **Both must be designed for.** Agency-oriented design preserves control and choice (bounded friction, human-in-the-loop oversight, transparency); identity-oriented design protects authorship and recognition (authentic assessment, clear attribution of AI vs. human contribution, tasks that let learners claim a domain). Protecting agency without protecting authorship keeps control but not self-worth — and vice versa.

This distinction between enacted agency and stable identity applies to refusal. As Zagami (2026) describes it, declining a chatbot for assessed writing, prohibiting it for unaided reasoning, resisting automated triage in student support, or delaying procurement are separate relations to separate systems, spanning personal, pedagogical, professional, administrative, and institutional levels rather than one durable disposition. That right is unevenly allocated: students with academic confidence can decline without penalty, while those needing language, accessibility, or rapid-feedback support read refusal as lost opportunity, and secure academics refuse on principle while casual staff feel pressure to adopt. Where AI sits in infrastructure, refusal is displaced from individual opt-out into procurement, audit, and contestability. - **Refusal as identity construction, not just a decision (students of color in apprenticeship learning).** Gyekye (2026) interviewed five secondary-school apprentices over 9 months and found they authored themselves through AI in three moves: refusal (non-use as institutional alignment), negotiation (repairing institutional mismatches, privacy as distant abstraction), and recognition (equating fairness with absence of visible bias — a "cultural flatness" in which their identities go unrepresented in AI responses). The study's two interpretive concepts — Institutional AI Literacy and Recognition Bandwidth — name the capacity to make AI use institutionally legible and the room students have to see themselves recognized in AI outputs. A five-student single-program narrative inquiry; its contribution is showing that AI use, limitation and refusal are bound up with how learners understand themselves as authors and emerging professionals.

The Ecological Co-Agency Framework: agency as an epistemic design problem

Poudyal (2026) reframes learner agency as fundamentally an *epistemic* concern: generative AI does not simply add a tool but reassigns epistemological authority — the ability to produce knowledge, validate claims, and create evidence of learning — from teachers to students to machines. The paper's **Ecological Co-Agency Framework** treats co-agency as the relationship between three interdependent dimensions, all bounded by a non-negotiable condition of human epistemic accountability:

- **Relational co-agency** — agency as a product of interaction among student, tool, and context, requiring transparent division of which tasks are delegated to AI and which retained, plus ethical co-agency in which humans retain primary accountability and act in a monitoring capacity.

- **Regulatory co-agency** — mapping the self-regulated learning cycle (forethought, performance, reflection) onto AI mediation. Whether GenAI enters *before* or *after* the learner's attempt determines whether it amplifies or erodes perceived control; strategic Cognitive Offloading supports transformative learning only when the offloading decision is intentional rather than routine.
- **Pedagogical co-agency** — placing teachers at the center, moving along an observer–adopter–collaborator–innovator continuum that depends on institutional support, not individual disposition.

The framework's boundary condition requires **contestability** (the ability to question and cross-check AI output), **provenance** (knowing where training data and output come from), and **non-delegation of moral and intellectual credit** (high-stakes judgments about student welfare, academic standing, and grades must not be determined solely by AI). This gives educators and policymakers a more precise vocabulary than the vague "balance" between human and artificial contributions, connecting agency to Ethics, Assessment, Equity, and AI Governance.

A closely related framing is **relational epistemic agency** (Du & Yuan 2026), which agrees that agency is socially enabled and technologically mediated rather than a matter of isolation from dependence. Where the Ecological Co-Agency Framework stresses human epistemic accountability as a non-negotiable boundary, Du and Yuan retain an explicit *asymmetry*: AI systems may shape and extend reasoning without possessing reciprocal responsibility or legitimate authority. Their six diagnostic criteria — contestability, recoverability, transfer, traceability, distributed responsibility, and epistemic plurality — provide a practical test for when a human–AI relation preserves the learner's capacity to participate in how claims are formed, assessed, and accepted, versus when it merely delivers a product. Agency on this account is not independence from tools but the capacity to judge responsibly *with, through, and against* the systems that mediate knowledge.

- **Delegated agency as a mechanism, not only a risk.** Yan and Gašević (2026) treat the delegation of cognitive work to AI as part of how learning happens, not merely a threat to it: in their account assisted performance becomes durable capability only when the learner keeps responsibility for framing the problem, setting criteria, and justifying answers, a division of labor they call delegated agency. That makes the allocation itself the design variable, since the same tool can preserve or dissolve learner agency depending on which responsibilities it absorbs.

Common Misconceptions

- **"Students exercise agency when they use AI freely."** A **14-category scheme coding 6,788 ChatGPT-assisted turns** placed **59% of seventh graders' turns** into categories that do not represent agentic use. Usage volume and agency are different measures.
- **"Current models support learner agency well." Benchmarked across ten models, supporting agency is where they do worst after learning**: ImpactBench measured **Agency and Purpose at 56.0%** on positive criteria. Agency is the dimension AI systems handle least well, not a by-product of capability.
- **"Teacher mediation is a constraint on agency."** Canonigo (2026) followed **ten secondary mathematics teachers across an eight-week ChatGPT-4** intervention and the mediation is the mechanism rather than the obstacle.

Learner Identity

> **Learner identity** — the evolving sense of who one is (and who one is becoming) as a learner, encompassing disciplinary, professional, creative, and academic identities. In AI in education, generative AI presses on learner identity in two directions at once: it can *support* identity formation (Scaffolding disciplinary belonging and confidence) while also *threatening* it (undermining perceived authorship, competence, and authentic learning). Understanding learner identity is central to designing AI that affirms rather than erodes learners' sense of self.

Questions to Consider

- Think of a time you felt a skill or piece of work was truly 'yours' versus merely done through you. What made the difference — authorship, recognition, competence? How might a tool that produces the work for you reshape that feeling?
- A common assumption is that identity is a fixed trait a learner either has or lacks. What would change in how you design learning if you treated learner identity instead as something continuously built through participation, recognition, and authorship?
- The page describes a 'competence paradox' among art and design students: AI tools feel easy and useful, yet their use threatens the creative identity students derive from manual craft. Have you ever felt your own competence or identity challenged by an easy tool? What was the tension?
- Students sometimes hide or feel shame about their AI use, which fragments their academic identity and honest engagement. When does the pressure to appear a certain kind of learner push people to conceal how they actually learn, and what would make disclosure feel safe?
- AI can scaffold identity formation as well as threaten it. If you were designing an AI learning companion, what specific features would protect a learner's sense of authorship and ownership while still offering support?

Introduction

Learner identity concerns who a learner understands themselves to be, and who they are becoming, within a domain — a motivational and developmental construct distinct from ability beliefs such as Self-Efficacy, which answer the narrower question *can I do this?* Identity forms through participation, recognition and authorship: seeing oneself reflected in a field and having that self-view validated by others. AI reshapes all three conditions, because it changes who does the work, what counts as one's own contribution, and whether a learner is recognized as the author of their own learning (Learner Agency, Metacognition).

Why identity matters for AI in education

Identity is a motivational and developmental construct distinct from (but connected to) related abilities and beliefs. Where Self-Efficacy concerns *can I do this?*, identity concerns *who am I — and who am I becoming?* It is built through participation, recognition, and authorship — through seeing oneself reflected in a domain

and having that self-view validated. AI reshapes the conditions under which identity forms because it changes *who does the work*, *what counts as one's own contribution*, and *whether a learner feels recognized as the author of their learning*. This makes identity a first-order design concern rather than a peripheral "soft" factor.

- **Authorship and competence under threat.** When AI produces text, images, or code, learners may question whether the result is truly "theirs" — a challenge to the authorship dimension of identity. **Liu et al. (2026)** document a *competence paradox* in art and design students using text-to-image GenAI: the tools feel easy and useful, yet their use simultaneously threatens the **creative identity** students derive from manual craft and authorship, producing a genuine tension between ease and self-worth.

A distinct authorship condition, not only a threat to authorship: when self-formative dialogue is habitually delegated to a conversational model, the authors argue the integrative work of authoring is *delegated* rather than undeveloped or absent — a self densely voiced yet un-authored, which they say existing constructs have no slot for (Du et al. (2026)). - **Shame and hidden use. Lin et al.** show that computing students experience shame and guilt around AI use, which function as social regulators driving *hiding* and selective disclosure — behaviors that can fragment academic identity and undermine honest engagement with learning. - **Identity as something AI can scaffold.** AI need not only threaten identity. **Benedetti (2026)** argue that accountable, relationally-oriented pedagogical accompaniment can support learners' **STEM identity** development by providing transparent, bounded support that leaves room for the learner to own their trajectory.

Identity in the knowledge base's research

- **Creative identity: the T2I competence paradox** captures how ease-of-use can undermine the craft-based identity of art and design students.
- **Felt authorship can decouple from actual originality.** Design students building websites with AI rated their authorship highly (67/100, satisfaction 6.4/7, perceived quality 6.1/7), yet those ratings tracked nothing measurable: their designs were more homogeneous than without AI, and felt authorship correlated with measured originality at $r \leq +0.13$ (Boussioux et al., 2026).
- **Professional identity:** multiple studies treat AI's impact on **professional identity** — for example, **Lodge et al. (2026)** argue that graduates need *adaptive capabilities* (AI Literacy, Distributed Cognition, Metacognition) precisely so they can sustain a viable professional identity in an AI-integrated future, rather than being defined by — or defined out by — their tools. GenAI judgments can split by temporal context as well as authorship: interviewees judged AI use inappropriate for learning yet legitimate or expected in future professional work — "As a student I must learn, as a professional I must produce" (Sun et al. (2026)).
- **Post-human and hybrid identity: Elsayed (2026)** theorize the **post-human learner**, whose cognition is genuinely hybrid and distributed across biological and artificial systems — a reframing of identity formation itself in the age of cognitive AI.
- **Student and academic identity: authentic assessment** research connects to identity because Assessment tasks that call for authentic, personal performance help students see themselves as

capable practitioners; **history-education research** shows how paternalistic AI use can shape how students construct their identity as disciplinary inquirers.

- **How students frame the tool shapes their professional becoming.** Students who cast GenAI solely as a socio-emotional partner produced less differentiated reflections on their professional learning than those who also framed it as a technique, a learning material, or a structure (Bohmer et al., 2026).
- **Guarded adoption: selective AI use as identity protection.** Zagami (2026) surveyed 484 students at one Australian university and found that higher-achieving students reported *lower* active generative AI engagement, lower positive affect toward AI, lower perceived learning impact and lower AI-related disengagement, with the strongest associations at rho = -0.395 for perceived learning impact and rho = -0.359 for positive affect. Their open-ended responses described use that was selective (clarification, summarization, workflow support), verified, and held subordinate to their own judgment, and item-level results showed greater agreement that reliance on AI hinders Critical Thinking and independent problem solving. The authors read this as identity work: for students whose sense of themselves as successful learners rests on their own effort and judgment, bounding AI use defends the epistemic agency the identity depends on — which also means the pattern is neither technophobia nor low engagement.
- **A stated purpose does not necessarily govern an AI decision.** Ting et al. (2026) interviewed 14 undergraduates and coded each interview for the relationship between the student's purpose — a personally meaningful intention to contribute beyond the self — and their AI choices. Only some made the connection: one refused AI because its environmental and human costs contradicted her purpose, and three let future professional identity shape their choices ("contributes to the psychologist that I will be out in the world one day"). Others with an equally clear sense of purpose made no such link, describing purpose and AI as "kind of separate," so having an identity to protect was not the same as drawing on it. The paper also separates the reasons students give for keeping work their own — skill development, ownership and pride, and moral objection — which arrive through different mechanisms and should not be pooled into one motive.

Relationship to learner agency

Learner agency and learner identity are closely related but distinct constructs that are easy to conflate — and both are central to how AI affects learning.

- **Agency is about *doing*; identity is about *being*.** Learner agency concerns the capacity to act intentionally, make choices, and exercise control over one's learning *in the moment* — a situated, interactional, and variable capacity. Learner identity concerns who one *is* and is *becoming* as a learner — a more durable, narrative, and developmental sense of self. Agency asks "am I able to direct this?", while identity asks "is this who I am / who I want to be?"
- **They are causally intertwined.** Agency is both a *source* and an *outcome* of identity. Enacting agency — choosing, authoring, persisting — is how a learner comes to see themselves as an agentic person (identity is partly internalized agency). Conversely, a stable disciplinary or professional identity supplies the motivation and self-worth that sustain agency under difficulty.

Identity is the accumulated product of repeated agentic acts; agency is the ongoing enactment that builds identity.

- **AI threatens them through different mechanisms.** AI can erode **agency** by inviting over-reliance and passive acceptance — learners stop directing their own reasoning. AI can erode **identity** by undermining authorship and competence — when AI produces the work, learners may stop feeling the output is "theirs" or that they belong in the domain. The competence paradox is an identity threat; implicit AI redistribution of epistemic labor is primarily an agency threat, though it compounds into identity over time.
- **Safeguarding both is the design goal.** Supporting agency means preserving learners' control and choice (e.g., bounded friction, human-in-the-loop oversight). Supporting identity means protecting authorship and recognition (e.g., authentic assessment, transparent attribution of AI versus human contribution). A design that protects agency but not authorship protects control without protecting the sense of self — and vice versa.

In short: **foster agency to let learners act; sustain identity so they know who they are while acting.** Healthy AI-supported learning attends to both.

Relationship to teacher identity

Learner identity is the **student-facing** counterpart to teacher identity. Teacher identity — the evolving professional self-understanding of educators — is documented on the Teaching page, where Laidlaw (2026) frame GenAI as an *identity crisis* for faculty rather than merely a skills gap, and TPK-based teacher training treats identity as part of professional preparation. The two are reciprocal: teachers who experience identity disruption are less able to support their students' identity development, so a healthy AI-integrated system must attend to both.

Connections

Learner identity connects to Learner Agency (identity is enacted through agentic authorship), Self-Efficacy (competence beliefs that sustain identity), Motivation and Self-Determination Theory (identity formation satisfies needs for autonomy and competence), Student Experience and Student Engagement, and STEM Education (where disciplinary identity is a key outcome and predictor of persistence). It is also shaped by Situated Learning and Critical Pedagogy (identity as participation and as power-laden negotiation) and connects to Authentic Assessment (tasks that let learners perform and thus claim an identity). Its Higher Education and K-12 relevance spans both schooling and professional preparation.

Common Misconceptions

"Learner identity is a stable trait a course can accommodate." It is better treated as something **continuously built through participation, recognition, and authorship**. That shift changes the design question from matching an existing identity to shaping the one the course makes available — and an AI that completes the work removes one of the three ingredients, since authorship is where the identity claim originates.

“Identity issues belong to students from under-represented groups.” Identity is formed in every learner by whether their participation is recognized, which makes it a general design condition rather than a special provision. Framing it as a targeted concern is how it gets deferred.

“AI assistance lowers barriers and therefore widens participation.” It can lower the barrier to producing work while narrowing the barrier to claiming authorship. A student who submits a fluent artifact they did not author has been given access to the outcome and denied the recognition that builds the identity behind it.

“Recognising a learner’s identity is a matter of representation in content.” Representation matters and recognition is enacted in practice: whose questions get taken up, whose contribution is credited, and who is treated as capable. A curriculum can be representative and still withhold the recognition that identity formation requires.

Design Thinking

> **Design Thinking** — a key concept in AI in education research: a human-centered, iterative Problem Solving process (typically Empathize → Define → Ideate → Prototype → Test) that moves learners from understanding a problem to producing and refining a solution. Explored across 8 articles in this knowledge base.

Questions to Consider

- Design thinking follows Empathize → Define → Ideate → Prototype → Test. In your own problem-solving, which stage do you naturally skip — and what might that cost you?
- Generative AI excels at early-stage ideation but can cause 'design fixation' or aesthetic lock-in if used uncritically. Have you ever latched onto a first AI suggestion and struggled to see alternatives?
- One study found that an adversarial AI that challenged designers produced more iterations, broader exploration, and better final designs — but was frustrating to use. When is friction with an AI genuinely productive?
- Students who used GenAI heavily in design reported it did NOT reduce their sense of ownership or creativity. Does that contradict the worry that AI erodes authorship — or does it depend on how the tool is orchestrated?
- Design thinking enters this corpus in two ways: as a skill learners are taught and assessed on, and as an approach teachers adopt when they create AI-supported learning. Which role is more relevant to your work, and how does that change the design principles you'd apply?
- In practice, most of the effort goes into iterative prompting and generation, while assessment of learner needs and feedback loops get neglected. What does it mean to treat AI as a 'fallible co-intelligent collaborator' rather than a content generator?

Introduction

Design thinking sits at the intersection of creativity, craft, and critique — and it is increasingly where Generative AI and Agentic AI are reshaping how students learn to design. Across this knowledge base's connected articles, design thinking appears in two distinct roles: as a *pedagogical object* (the skill being taught and measured) and as a *pedagogical method* (the process educators themselves use to build AI-supported learning). In both roles, the same tension recurs: generative tools can accelerate ideation and broaden participation, but their value depends on how they are orchestrated, on the Feedback they provide, and on whether the learner retains a genuine sense of Learner Agency.

Evidence from the knowledge base

- **GenAI in design studios and architecture.** Two architecture-focused studies ground the concept in studio pedagogy. Gen-AI-tecture found that a locally executed, discipline-specific tool

enhanced creative fluency, broadened participation across diverse learner profiles, and strengthened confidence in AI-supported workflows — an important signal for Equity as visual-spatial design becomes more accessible. GenAI in architectural design studios likewise found students using GenAI as visual stimuli and inspirational resources in early ideation, and as a combinatorial method for expanding the solution space during development. Crucially, both warn that without critical discernment students risk **design fixation** or aesthetic lock-in, reframing the Teaching in Higher Education from transmitting craft to coaching how, when, and why to delegate creative exploration to generative models. Creativity is thereby preserved and even amplified — but only under careful pedagogical orchestration.

- **Adversarial AI agents prompting reconsideration.** Constructive conflicts with AI agents takes design thinking toward Agentic AI, testing adversarial versus cooperative AI roles with novice interaction designers (N=48). The adversarial condition produced significantly more design iterations, broader exploration of alternatives, and higher-rated final designs — participants found the conflict agent frustrating but ultimately helpful. This productive-friction dynamic, echoing the Socratic Method and Scaffolding, shows that design thinking benefits from challenge rather than mere assistance, a finding with implications for how Student Experience is designed in AI-augmented studio settings.
- **Design thinking as a student skill being developed.** GenAI usage by design students at Politecnico di Milano reported very frequent use concentrated in early, ideation-heavy stages — yet high adoption did not reduce perceived project ownership or creativity, directly informing AI Literacy and Academic Integrity debates about authorship and process transparency.
- **AI in design pedagogy and educator frameworks.** It also shapes how teachers construct AI-supported learning experiences. GAIDE offers a Design-Thinking-based framework for K-12 teachers creating AI-powered tools through vibe coding, raising teachers' AI literacy and supporting learning-by-creating as Educational Development and Workplace Learning. The DOT Framework survey (n=72) grounds design thinking in open-systems theory and found practitioners frequently use iterative prompting and content generation but underuse needs assessment and feedback loops — a practice-versus-theory gap that operationalizes AI as a fallible co-intelligent collaborator under Human-in-the-Loop oversight. Even co-creating open social robots with students applied the Double Diamond (a design-thinking variant), redesigning the build around accessibility so that repairability and Open Source principles become sites of continued learning.

The mindset itself is measurable, and it moves across a program. Liu et al. (2026) validated five design thinking mindset dimensions in 409 AIGC-using fashion film students and found third-year students higher on all five, with abductive reasoning (0.865) and creative confidence (0.760) the largest standardized differences — a design education outcome that generated alternatives alone does not evidence.

Practical guidance

For educators, the collective evidence counsels against blanket restriction or unfettered adoption. Treat GenAI as an *ideation resource whose value is orchestration-dependent*: it excels at early-stage exploration and empathise work, while human instructors add contextual anchoring in prototyping and evaluation. When deploying Agentic AI agents, consider adversarial or Socratic roles that prompt reconsideration rather than

smooth cooperative confirmation. And for designers of teacher-facing support, remember that beliefs alone are not enough — practitioners need scaffolding for the full design cycle (needs assessment, feedback loops), not just tool usage, and evaluation instruments to verify that design thinking is actually being developed (see AI Ed Evaluation).

Connections to related concepts

Design thinking in AI education is deeply entangled with Human AI Collaboration: generative tools broaden ideation while humans retain epistemic authority and Learner Agency. It relies on Scaffolding and stage-appropriate Feedback to be effective, is often delivered through Socratic and adversarial interactions in Higher Education and K-12, and its success is frequently framed as preserving Creativity and fostering AI Literacy under Human-in-the-Loop governance.

Common Misconceptions

“Generative AI accelerates design thinking across all its stages.” It accelerates ideation and can degrade the judgment the later stages depend on: it **excels at early-stage ideation but can cause design fixation or aesthetic lock-in if used uncritically**. Fixation is the specific hazard of a fast ideation tool — the first plausible direction becomes the frame, and a large set of variations on one concept is not a wider search space.

“More generated options mean a broader exploration.” Breadth of output and breadth of consideration are different quantities. A student who generates thirty directions and adopts the first convincing one has explored one direction, and high acceptance rates are the signature of exactly that.

“Design thinking is a process to be automated stage by stage.” It is a discipline of framing and reframing problems, which is what fixation forecloses. Automating the stages while leaving the frame unexamined produces competent output for the wrong problem.

“AI agents that agree with the student support their design reasoning.” The productive use documented here runs the other way: constructive conflicts with AI agents tests adversarial prompting that forces reconsideration. An agreeable agent reinforces the fixation; a dissent-oriented one is the design with an educational claim behind it.

Curriculum Design

> **Curriculum Design** — the process of planning and structuring what is taught across courses, programs, and institutions, including learning objectives, content sequencing, assessment strategies, and skill progression. In the AI era, curriculum design must balance foundational knowledge with emerging AI competencies, determining not just what students learn but how they learn to work with and critically evaluate AI tools.

Questions to Consider

- Curriculum design asks what students should learn at the program level, while learning design asks how at the course level. When AI reshapes a discipline, which of these two layers do you think should change first?
- As generative AI automates implementation-level work, some argue curricula must shift toward system design, abstraction, and critical evaluation. What do you think students would lose if low-level skills were de-emphasized?
- Curriculum redesign in the AI era is often framed as a balance between tool fluency and foundational knowledge. Where have you seen that balance tip too far in one direction?
- The SAIL framework treats AI literacy as scaffolded across ages and designed to address deeper 'digital divides' beyond access. How is embedding AI literacy across a whole curriculum different from adding a single AI course?
- If every discipline now needs AI competencies embedded within it, who is responsible for the curriculum change — instructors, programs, or institutions — and what do educators need to succeed at it?
- A curriculum is a sequence of skills across years, not just a list of topics. How does that longer view change whether an 'AI literacy unit' actually sticks?

Introduction

Curriculum design addresses the *what* of education at the program level, complementing Learning Design which addresses the *how* at the course level. The articles in this knowledge base explore how AI is reshaping curricula across disciplines — from software engineering to architecture to green education — and how educators are designing curricula that embed AI literacy without sacrificing disciplinary fundamentals.

Key research themes

Redesigning curricula for the AI era is the central challenge. **Lee et al.** synthesized findings from international workshops on reshaping undergraduate CS education, arguing that as GenAI automates implementation-level programming, curricula must shift toward system design, abstraction, and critical evaluation — while de-emphasizing low-level implementation details. **Gorsky** formalized Agentic Software

Engineering as a distinct discipline with a 21-module curriculum focused on the “evolution of intent” and practitioner discipline required to manage AI agents. Both connect to AI Literacy and Scaffolding.

Reviewing the change as systemic rather than additive, Sabani et al. (2026) triangulate a scoping review, bibliometric mapping of 209 records, 36 articles, and ten academic-leader interviews into five shifts — including knowledge transmission giving way to capability development and local experimentation to institutional governance.

Curriculum mapping and analysis uses AI to understand existing curricula. **Geng et al.** analyzed 23 syllabi from AI-assisted software engineering courses, identifying common themes — prompt engineering, code review with AI, ethical considerations — and deriving design guidance that emphasizes balancing tool fluency with foundational knowledge. **CourseGraph** applies computational methods to compare CS course structures across institutions.

Weighting changes what a curriculum analysis reports: Jayalath et al. (2026) had GPT-o3-mini distribute 100% across seven enterprise skills for each of 48 assessments, reaching a Krippendorff’s alpha of 0.81 against expert weights, but agreement turned negative for skills the descriptions never state explicitly (-0.19).

Modular structure outlasts current content. A pattern recurs where the field moves faster than the review cycle: a stable core of AI literacy, critical appraisal, bias detection and Ethics, with specialty and locally available tool content attached as modules and revisited every six to twelve months (Bursic et al. (2026)). Postgraduate medical education is the stated case, but the principle generalizes: the program commits to competencies that survive tool turnover and schedules the tool-specific layer for replacement.

AI literacy integration embeds AI competencies across disciplines. **SAIL** provides a scaffolded AI literacy framework applicable across all ages and educational stages, addressing second- and third-level digital divides. **Tracing GenAI Literacy: Student-AI Interaction Patterns in Academic Writing** examines how AI literacy develops through interaction patterns. **Systematic review of collaborative learning activities for promoting AI literacy** explores collaborative approaches to AI literacy curriculum development, connecting to Collaborative Learning.

LearnAI shows what an embedded version looks like: a wide-exposure layer of short presentations inside 18 existing courses across five disciplines (293 students), paired with opt-in one-to-one co-creation sessions run by trained undergraduate peer tutors, so mixed-ability learners meet AI tasks at their own level (Qu et al. (2026)).

Integration in practice lags the frameworks. Santos-Albardía et al. (2025) found only 13.8% of surveyed education and journalism students said their coursework addressed critical media analysis, against 97.8% who rated it important, and their expert interviews traced the gap to teacher training that prioritizes technical and instructional skills over media education.

A PRISMA review of 39 STEAM studies (2016–2025) found a parallel imbalance in AI-literacy elements: implementations developed technical literacies — fundamental AI concepts, computational thinking, data literacy — while underdeveloping ethical awareness, creative imagination, and creating, managing and designing with AI, so auditing each unit against them is the practical response (Niri et al., 2026).

Student voice is another design input: 84% of 166 final-year business students wanted GenAI taught in their units and 85% saw it as essential for employability, while only 7% had learned about it from their university (Rook & Plumb (2026)).

A 42-study review of pre-university AI education finds curricula moving from technical content toward competency-based models built on frameworks such as AI4K12 and the Five Big Ideas in AI, with AI Literacy treated as a cross-curricular competency while standardized instruments for assessing it remain absent (Caruana et al. (2026)).

Instructors and employers agreed on the importance of only one of 26 AI skills — setting realistic expectations for AI-augmented work — and just three of the 26 were taught by half or more instructors, the report's evidence of an AI skills gap between higher education and employers (Fried (2026)).

K-12 ML activity design stays at the surface: a review behind the ICE-T framework found that invisible use, button interaction, and model deployment account for almost 60% of coded supervised-learning activities, open-ended creation appeared only twice, and technical and societal perspectives co-occurred in only about 3% of activities (Haritz et al., 2026).

Domain-specific curriculum innovation applies curriculum design to specific fields. **Gen-AI-tecture: using generative AI to support architectural students in design tasks** explores how generative AI reshapes architectural design Pedagogies and Teaching Strategies. **The Role of Artificial Intelligence in Green Education: Optimizing Teacher Workflow and Enhancing Pedagogical Design under Sustainable Development Pedagogy (SDP) Constraints** examines AI integration in green education curricula. **ConnectED: A curriculum-aligned AI system for Vietnamese instructional lesson planning and student learning** and **LLMs to Support K-12 Teachers in Culturally Relevant Pedagogy: An AI Literacy Example** address culturally responsive curriculum design.

Embed AI inside the discipline rather than beside it. A three-tier (introductory, application, advanced) AI curriculum folded machine learning into existing thermal-engineering topics across a 39.1-hour course rather than adding computer-science electives, avoiding extra load on mechanical-engineering students and releasing its syllabus, data and code openly (Li et al. (2026)).

A journalism case shows the values-first variant: a triadic values–processes–competencies scaffold moved students from human-only reporting to AI-integrated work, yet 8 of 9 (89%) reported confidence in ethical decisions while survey items on authorship and bias suggested only superficial understanding (Ngu and Weller (2026)).

Institutional frameworks address curriculum change at scale. **A principled way to think about AI in education: guidance for educators and policy makers on action based on goals, models of human learning, and use of technologies** and **A principled way to think about AI in education: guidance for educators and policy makers on action based on goals, models of human learning, and use of technologies** provide principles for integrating AI across educational programs. **The Main Barrier to AI Adoption in the Public Sector is Lack of Training** examines barriers to AI curriculum adoption in public sector education.

Sequencing AI across the program. Torres-Sahli et al. propose a "refrain, then amplify" framework that sequences generative AI at the program level: withhold a generative tool while a capacity is forming, then restore it to amplify that capacity once the student can direct it and judge its returns. Governed by a forming-versus-offloading criterion (whether a stretch of work builds a capacity or merely passes it through the tool), the framework links curriculum design to Cognitive Offloading, Self-Regulated Learning, and Academic Integrity, with hard-to-fake checkpoints at each refrain-to-amplify hinge.

The lever for the highest stages is not more coursework: across 89 sponsored capstone projects, advancement from Workforce Readiness Level 6 to 7 was gated by industry-embedded experience — co-ops and Manufacturing Extension Partnership projects — so degrees need work-integrated learning rather than another technical elective (Smith et al. (2026)).

A curriculum-level consequence of model capability is that AI-resistant design expires. Computing educators described calibrating assignments against what the models could not yet do and watching the calibration lapse — one cybersecurity instructor's problems required genuine problem solving seven or eight months earlier and were then simply solved — with a facilitator estimating a shelf life of about one semester. The workshop's structural finding is that nearly every adaptation was made by an individual instructor within a single course, without the institutional coordination a durable curricular response would require (Akbar et al., 2026).

Whole-course alignment when generative AI is permitted. A 2026 redesign of an introductory nuclear and particle physics course (Mikhasenko et al.) integrated three activity types with distinct roles — lectures for concepts and notation, tutorials for standard analytic practice, and homework as an exploratory "research-shaped" component of unusually difficult, multi-method problems. The reported friction (an undeclared programming prerequisite, insufficient time to understand rather than merely obtain answers, and misalignment among lectures, tutorials, homework and examination) illustrates that permitting generative AI forces curriculum alignment work across the whole course rather than a change to one assignment type; their recommended structure keeps the AI-permitted exploratory work as bonus-bearing advanced tasks while the unaided written exam determines the grade.

Depth of alignment, not frequency of use, separates integration patterns. Across 17 business-module cases, six embedded GenAI systematically across teaching, learning and assessment (constructive), nine did so inconsistently (blended) and two sporadically (ad hoc); the constructive cases reported the strongest engagement, capability and curriculum-relevance outcomes (Zhou et al. (2026)).

Constructive alignment advice under critical scrutiny. Where the sources above report on alignment in practice, McInnes et al. (2026) read the guidance itself as a discourse. Their critical discourse analysis of 14 pieces of gray literature published from November 2022 to April 2025 — mostly institutional pages and chapters from centrally positioned learning and teaching units — found constructive alignment presented as an efficiency problem: generative AI was "an effective and efficient way to draft rubrics" that could "streamline the process", anthropomorphized as "an educational expert and assistant", a "sparring partner" or an "intelligent assistant in instructional design", while academic staff supplied only "subject matter expertise" and the tool took on "the heavy lifting of developing learning objectives, organizing course content … and aligning course components". Copy-and-paste prompt recipes and numbered templates framed CA as a standardisable product, producing three failure modes: performativity (alignment that only looks aligned), erasure of situated and critical context, and shallow CA that conflates alignment with the constructive dimension. Their remedy re-sequences the curriculum-design workflow — educators must understand CA well enough to direct, evaluate and reject AI output before delegating any part of it — and bounds any tool to an institutional retrieval-augmented agent grounded in local policy, rubrics and graduate attributes, with a "liminal tutor" role that extends rather than replaces the developer relationship.

Generating curriculum-aligned modeling tasks. AI-powered platforms can address teachers' lack of time and resources for designing high-quality mathematical modeling tasks by generating curriculum-aligned

problems and pedagogical recommendations grounded in design principles and retrieval-augmented generation — an approach illustrated with direct variation in secondary school mathematics (Creating an AI-powered platform for generating modelling problems: A case study on direct variation in secondary school mathematics). Course readings themselves are now a generation target too: Sidorkin (2026) replaced a commercial textbook with weekly AI-generated readings in a graduate educational leadership course, and although students rated them useful and 75 percent agreed they learned more than in a comparable course, the 4,487 pages of logs carried APA-style in-text citations on only about 0.80 percent of pages and paired a named campus or system with assertive policy claims on roughly 1.03 percent of pages without a verifiable source. The curriculum-materials lesson is to treat generated readings as draft production under instructor review, to budget for the instructor labor of prompt design and verification, and to curate vetted sources into the assistant rather than leaving source quality for students to infer from context.

AI-assisted lesson planning at the curriculum-into-classroom layer. At the point where a curriculum becomes a taught lesson, Luo and Tahir (2025) experimentally compared teacher-generated versus ChatGPT-assisted plans in children's STEAM arts education, finding AI-assisted plans rated significantly higher by six expert professors (median 20.5 vs. 17.6, p = .002, large effect). They show the payoff depends on how the teacher delegates: the recommended method fills content gaps in a self-outlined lesson (preserving teacher design autonomy) rather than delegating the whole plan. They also contribute a Role–Instructions–End Goal prompt template for reproducible, quality-controlled generation — evidence that AI lesson planning is strongest when embedded within, not substituted for, the teacher's curriculum decisions. In science education, expert validation reaches a parallel verdict on platform design: Karaismailoglu, Surmeli and Yildirim (2026) had eleven Science Education specialists rate ChatGPT-4 and an education-focused tool (Teacher's Buddy) on sixth-grade plans aligned to Turkey's revised curriculum and the Engineering Design-Based Learning model. The education-focused platform scored higher across all eight quality criteria — including feedback-intensive stages and curriculum alignment — evidence that embedding pedagogical structure into an AI yields better-aligned output. Yet some experts still preferred the general-purpose plan for its stronger social-emotional emphasis, and 7 of 11 judged the plans "applicable by correction" rather than directly usable. The choice of platform and prompt framing, not just the AI itself, shapes how well generated plans align to curriculum standards and process models.

Structure, not prompt phrasing, is what makes AI drafting reliable in production: Paiva (2026)'s Curriculum-as-Code pipeline pruned context aggressively and generated materials section by section across 28 project contexts, which cut instructor preparation time from roughly eight to two hours per instruction and left no conceptual or mathematical hallucinations for human review to catch.

Connections to related concepts

Curriculum design connects directly to Learning Design — curriculum defines what, instruction defines how. It connects to AI Literacy because embedding AI competencies is a primary curriculum challenge, to Teaching and Educational Development because curriculum change requires educator preparation, and to Scaffolding because well-designed curricula scaffold skill development across courses and years. The Higher Education and K-12 connections reflect curriculum design's relevance across educational levels.

Choosing one AI literacy framework means choosing a vocabulary nobody has crosswalked. In a scoping review of 50 K-12 frameworks, Kharbach et al. (2026) found competency definitions converging on

cognitive, affective, behavioral, ethical and social dimensions while the labels and constructs did not align. Only the ABCE framework approached a shared measurement tradition, validated across Hong Kong, Shanghai and Taiwan, and progression across grade bands was proposed repeatedly and tested nowhere.

Common Misconceptions

- **"An Large Language Models (LLMs) can map a curriculum once validated at high reliability."** GPT-o3-mini distributed **100% across seven enterprise skills for each of 48 assessments**, reaching **Krippendorff's alpha of 0.81** against expert weights — and **agreement** broke down on particular skills. High overall reliability with uneven agreement is the pattern to check before trusting the mapping.
- **"Embedding AI literacy means adding a course."** LearnAI shows the embedded form: a **wide-exposure layer of short presentations inside 18 existing courses across five disciplines (293 students)**. The exposure was distributed across the curriculum rather than gathered into a unit.
- **"Students arrive already able to evaluate media critically."** Only **13.8% of surveyed education and journalism students** said their coursework addressed critical media analysis, against **97.8% who rated it important**. The gap between valuing a skill and being taught it is the curricular opening.

Connected FAQs

- How Should I Incorporate AI Literacy into My Course?

Critical Thinking

> **Critical thinking** — the ability to analyze, evaluate, and synthesize information — is both a skill that AI tools can help develop and a competency that students must apply when using AI. In AI in education research, critical thinking appears in two interrelated forms: as a learning objective (teaching students to think critically) and as a safeguard against uncritical AI reliance.

Questions to Consider

- How confident are you in your ability to spot a false or misleading AI-generated answer? Research suggests self-reported AI competence far exceeds actual evaluation ability — how would you test yourself?
- Critical thinking here appears in two forms: a skill to teach, and a safeguard against uncritical reliance on AI. Can you think of a situation where a tool that 'teaches' critical thinking is actually training its opposite?
- One study found that having students interrogate AI-generated mistakes produced large gains in higher-order thinking. How might deliberately exposing errors — rather than hiding them — be a more powerful teaching move than you assumed?
- Easy access to AI answers can displace critical engagement before students realize it. What design feature, rather than a policy or a ban, could keep the cognitive effort alive?
- AI advice has been shown to suppress the willingness to say 'I don't know' — even when the advice is wrong. How does that change what it means to create a classroom culture where questioning is safe?

Introduction

Critical thinking is central to AI Literacy — students who cannot critically evaluate AI outputs are vulnerable to Over-Reliance, hallucinated information, and biased recommendations. Research on Cognitive Offloading shows that easy access to AI answers can displace critical engagement, while Socratic approaches that withhold direct answers preserve the cognitive effort necessary for deeper thinking.

Structured dialogue control, not a better prompt, is what separates a fallacy tutor from a debating chatbot: routing each turn through Toulmin-based intent detection, a fixed strategy order and a verifier agent let one Socratic system pass 84.5% of dialogue-quality metrics against 61.5% for a heuristics baseline (Shi et al. (2026)).

Critical thinking in AI education research

The knowledge base's articles explore critical thinking through design-based and empirical lenses. Adversarial AI agents enact constructive conflict to prompt reconsideration in novice designers — a Socratic variant that forces critical re-evaluation. RCT research on GenAI in teaching raises the question of whether AI tools that optimize for surface-level outcomes may inadvertently suppress the critical thinking that leads

to deeper learning. Measured evidence sharpens the point: whether critical thinking moves depends on how AI-mediated feedback and tasks are designed, and on learners' metacognitive regulation, not on access to a model.

GenAI use's link to self-reported critical thinking ran almost entirely through GenAI Feedback Literacy: in 421 Chinese undergraduates, feedback literacy mediated 71.98% of the total association (β=0.185), and the residual direct path was positive only for less reflective students (β=0.177) and non-significant for more reflective ones (Yan et al. (2026)).

The corpus also carries the pessimistic reading in argument rather than measurement. Muñiz and Castro Samayoa (2026) argue that the dominant usage pattern erodes critical thinking, not access to a model. They rest this on Dewey's claim that thinking improves only through exercise, and on three mechanisms: removed friction, automation bias, and an efficiency frame. The tension with Zhao et al. is real and unresolved in the corpus. Their meta-analytic gain of g = 0.609 describes designed interventions, while Muñiz and Castro Samayoa describe typical use. Read together, the two agree that the design variable is what matters, and disagree about what the unmanaged default looks like.

A meta-analytic anchor for the moderation claim. Across 29 experiments GenAI raised higher-order thinking moderately (g = 0.609), with critical thinking at ES = 0.691 — below Problem Solving (0.745) and above Creativity (0.444) — strongest for 8–16-week interventions (0.759) and for high-SRL learners (0.863 against 0.284) (Zhao et al. (2025)).

Reviews of ChatGPT's impact on thinking document mixed findings: AI can scaffold critical analysis when used deliberately (e.g., asking students to critique AI-generated arguments), but it can also short-circuit thinking when used as an answer engine. This tension connects to How to Assess AI Literacy: Misalignment Between Self-Reported and Objective-Based Measures research showing that self-reported AI competence far exceeds actual critical evaluation ability. A critical review of 80 HCI studies of critical thinking with AI found the field measuring what it rarely defines: only 23 of the 80 stated how they understood critical thinking at all, 49 (61%) assessed it through self-report rather than performance, and 42 (52%) used no control group (A Critical Review of Critical Thinking in HCI Research About AI).

Lin and Al-Hada (2026) read that mixed picture as a product–process dissociation: GenAI can raise the quality of an assignment while lowering the unaided, delayed transfer behind it, so learning should be judged on unaided delayed performance rather than on the AI-assisted product.

- **Higher-order cognitive engagement in student-AI chat.** Chang and Li (2026) find that ~62% of student prompts to AI encode higher-order cognitive demand, with Bloom-level profiles varying by discipline (STEM Apply-prevalent 20.8%, language Understand-prevalent 31.7%, social science Create-prevalent 33.8%). Their within-person design shows the same students produce significantly more higher-order prompts in social science than STEM courses ($p < .001$), indicating that disciplinary context shapes critical and higher-order engagement with AI.
- **Interaction patterns cluster by Bloom level and prior knowledge.** In an inquiry-based data-science writing task, 19 students produced 14 Large Language Models (LLMs) interaction patterns that varied by prior-knowledge level, and the design implication was to aim scaffolding at specific higher-order thinking stages rather than at LLM use in general (Luo et al. (2026)).

- **AI as a catalyst for critical media literacy in children.** Demir and Akar (2026) evaluate an 18-hour, 5E-model critical media literacy program for fourth-grade Turkish students in which generative AI (ChatGPT, Grammarly) acted as a pedagogical agent embedded phase-by-phase rather than an add-on. Paired-samples comparisons showed large gains in media reading (+3.50), writing (+1.67), and total media literacy (+5.17, all $p < .01$), with between-group post-test effect sizes of Cohen's $d = 1.12$ (reading), 1.18 (writing), and 1.31 (total literacy) favoring the AI-supported group. Qualitative analysis (interviews, student posters/drawings/slogans, classroom observation) surfaced six domains of critical media literacy growth — digital self-protection and data privacy, purposeful and responsible media use, safe communication and boundary awareness, critical evaluation and misinformation awareness, online risk awareness, and media Ethics/digital citizenship — indicating that deliberately interrogating AI-mediated content can cultivate critical analysis and reflection in young learners.
- **Dimension-specific critical-thinking gains in primary multimodal writing.** Lu et al. (2027) followed 60 Grade 5 students through an eight-week Conversational AI-supported multimodal writing practice in which they turned narratives into AI-generated images and short videos. Repeated-measures analysis across six critical-thinking dimensions found sustained gains (T1 → T2 and T1 → T3) in interpretation, analysis, evaluation, and explanation, a short-lived self-AI Regulation in Education gain, and **no change in inference** — an uneven, dimension-level pattern that an aggregate critical-thinking score would have hidden. The authors argue the AI-generated visuals *externalized* meaning and thereby lowered the inferential demand writing normally imposes, while peer collaboration (peer questions that forced inferring others' interpretations) supplied the occasions for inference the solo AI interaction did not. The design lesson: multimodal AI composing supports several critical-thinking facets but should be paired with continued Scaffolding and structured peer exchange to preserve inference and self-regulation.
- **AI scaffolding and offloading pull critical thinking in opposite directions.** Davor, Larbi and Boateng (2026) surveyed 533 university students in Ghana and found that AI task scaffolding predicted higher critical thinking ($\beta = .185$) while cognitive offloading tendency predicted lower critical thinking (-.240); AI verification literacy had no direct effect on critical thinking and worked only through metacognitive self-regulation, a full mediation pattern the authors read as evidence that teaching students to fact-check AI is not enough on its own. (Davor et al. 2026)
- **Offloading depth, not use, bounds higher-order thinking.** Delegating the reasoning layer of writing — warrants, counterarguments, evidence interpretation — carried the strongest negative association with independent higher-order thinking ($ab = -0.34$), and self-regulated writing weakened but never reversed it (Chen (2026)).
- **Dependence, not use, is where the association with critical thinking turns.** Shojaei and colleagues (2026) surveyed 412 business students in Oman and found a near-zero bivariate correlation between GenAI use and self-reported critical-thinking disposition ($r = 0.050$), with dependence predicting lower disposition ($\beta = -0.389$) and weakening the link from use to disposition ($\beta = -0.239$), so that the simple slope fell from 0.424 at low dependence to -0.054 at high dependence. (Shojaei et al. 2026)

A larger cross-sectional survey points the other way: among 1,157 Chinese graduate students, GenAI dependence was positively associated with critical thinking (β = 0.492), and critical thinking carried roughly 85.0% of the path from functional dependence to research creativity (Yin et al. (2026)).

- **Prior knowledge and task timing set the sign of the effect.** Across 108 reviewed documents, GenAI raised critical-thinking performance for experienced researchers (+0.20) and lowered it for novices (−0.13); early access helps under time pressure but impairs critical thinking when deliberation time exists (Zapata-Hernandez et al. 2026).
- **A short reflection prompt makes reliance on AI advice more discriminative.** In a three-condition experiment with 342 undergraduates, Ren (2026) found that open ChatGPT support produced acceptance of incorrect AI recommendations on 62.4% of trials, falling to 39.7% with a brief metacognitive reflection prompt (OR = 0.40, 95% CI [0.28, 0.56]); reflection also improved awareness calibration (0.59 vs. 0.41) and cut the AI-specific attribution bias index from 0.42 to 0.21 without reducing recommendation accuracy or triggering blanket rejection of useful advice. (Ren 2026)
- **Confidence can rise while accuracy falls.** Shaw and Nave (2026) found that consulting an AI assistant raised accuracy by 25 percentage points when it was right and lowered it by 15 when it erred, yet engaging it increased confidence even after errors, and 73.2% of incorrect-AI trials ended in surrender rather than strategic offloading.
- **Teacher-curated ChatGPT feedback raises critical thinking through higher-order revision.** Chen and colleagues (2026) ran an 18-week quasi-experiment with 64 undergraduates, all pre-service chemistry, physics or mathematics teachers, comparing conventional teacher feedback (n = 32) against ChatGPT-assisted teacher feedback (n = 32) across two argumentative writing tasks. The groups began equivalent, and only the assisted group improved significantly ($p < 0.001$), with Cohen's *d* rising from 0.25 at pretest to 3.74 at posttest. The mechanism was the kind of feedback, not the mere presence of a model: the assisted group received more demonstration (33.1% vs. 10.9%) and closely questioning (21.5% vs. 6.0%) feedback, revised 91.00% (435 of 478) of feedback units against 85.21% (242 of 284), and epistemic network analysis linked those revisions to analysis, evaluation and creation rather than recognition and understanding, while teacher-only instruction and evaluation feedback mostly produced recognition and understanding revisions. Teachers treated the model's output as draft material, expanding, revising or discarding it (14% discarded, 9% needing correction), and six of eight interviewees still flagged imprecision or unprofessionalism. The design lesson is that the critical-thinking gain came from feedback that models alternatives and interrogates the student's reasoning, with a teacher curating what the model produced; the small, single-semester sample means the very large effect size should be read with caution. (Chen et al. 2026)
- **A semester of AI access left critical thinking flat, while reflective use tracked it.** Melanou, Beege and Kimmig (2026) followed 87 business informatics students through a nine-week course in three parallel conditions (tutor-framed AI, unguided AI, and no AI) measured three times. Knowledge rose in every group with no advantage for either AI condition and no Matthew effect (BF01 = 8.70), while self-reported critical thinking and Motivation stayed stable. What separated students was reflective use, the practice of checking sources and verifying AI output before

adopting it: it was higher in the AI condition than in the control group (means of 3.72 vs. 2.82) and predicted critical thinking at the final measurement ($R^2 = 0.183$, $\beta = 0.43$, $p < 0.001$). The result qualifies any expectation that a course of AI use will move critical thinking on its own: metacognitive regulation, not tool access, is where the association lives, and the authors note a semester is likely too short to see durable change. (Melanou et al. 2026)

Connections to other concepts

Critical thinking intersects with Scaffolding (designing AI support that maintains cognitive demand), Prompt Engineering (formulating questions that elicit critical analysis), and Over-Reliance (knowing when to trust and when to question AI). It is foundational to Academic Integrity and serves as a key dimension of AI Literacy frameworks across both K-12 and Higher Education contexts.

- **AI errors as provocations for higher-order thinking:** Hosseini (2026) operationalizes Bloom's higher-order levels (Analyze, Evaluate, Create) by having students interrogate AI-generated mistakes in a database course, with significant pre/post gains (Cohen's *d*=1.49) in subject-matter competency.
- **Critique of AI output is a scaffoldable skill, not a by-product of problem-solving.** Groups that only solved a related physics problem accepted a polished AI solution or critiqued it from their own Misconceptions about AI, whereas MAPS-rubric-guided reflection produced expert-aligned critiques of missing integration and undefined notation (Borse et al. (2026)).
- **Bound the AI to preserve cognitive agency.** The E3-HOT blueprint maps three embodied pathways — situational embedding, embodied participation, cognitive creation — onto Analyze, Evaluate and Create, and constrains the AI to prompts, critique and strategy suggestions so students must articulate rationales and cite evidence before a claim is accepted (Zhu et al. (2026)).
- **Two-sided auditing of AI explanations.** Bernstein and Sibia (2026) used Paul–Elder standards (accuracy, clarity, assumptions, point of view) as interview probes with ten students who had completed CS2, and found mechanism-level scrutiny of GenAI explanations: students located where an analogy's mapping broke (an island-route analogy for a linked list that implied a circle, a badminton rally offered for recursion that had no guaranteed shrinking input), demanded precise wording over hedging, and treated explanations as arguments carrying a point of view. Crucially, that scrutiny tracked source- or target-domain expertise rather than personal interest — reframing critical evaluation of AI output as a knowledge problem ("two-sided analogy auditing") rather than a dispositional one — and suggesting that assigning flawed AI analogies as objects to inspect and repair is a harder check on conceptual understanding than reading a finished explanation. (Flawed but Memorable: Student Critical Reception of Interest-Personalized GenAI Analogies in Computing Education)
- **Critical thinking as non-outsourceable engagement.** Xie (2026) adds a philosophical counterpart from Daoist self-cultivation: because AI is an opaque "black box," a framework oriented to harmonizing uncertainty rather than adjudicating truth in absolute terms better suits the current epistemic landscape, and critical thinking becomes sustained, first-person, non-outsourceable engagement with reality rather than a demonstrable rational procedure. In Neidan (内丹) practice "there are no cognitive shortcuts," so AI is positioned as "not a cognitive surrogate

but an instrumental adjunct" to human flourishing.(Alternative AI Philosophy: Daoism as Method for AI in Education)

- **Role rotation as a structure for critical human-AI interaction.** Kenzhebayeva and colleagues (2026) report a design-based study in which 62 pre-service educational psychologists rotated through four professional roles (Case Constructor, Research Analyst, Practitioner-Interventionist, Reflective Researcher) that made generated recommendations the object of discussion. Participants compared AI output with psychological theory and modified or rejected recommendations that did not fit the case, and later cycles showed more requests for theoretical justification, while overreliance on apparently authoritative responses persisted. (Kenzhebayeva et al. 2026)
- **Verification-centered integration in a discipline.** A critical review of generative AI in university chemistry education (Vega-Baudrit and Rivera Álvarez, 2026) argues that because chemical reasoning must be coordinated across macroscopic, submicroscopic, and symbolic representations, students cannot verify what they do not understand, so Prior Knowledge and Scaffolding come first and verification should be designed into Assessment as an assessed activity: identify a false assumption, correct a unit or mechanism error, or justify rejecting a generated answer, keeping prompt logs and revision histories as reasoning traces. (Vega-Baudrit and Rivera Álvarez 2026)
- **Verification as a learning activity, not only a safeguard.** Wang (2026) organizes AI-artifact evaluation around six interdependent dimensions — Process, Evidence, Access, Reproducibility, Legitimacy and Source — and treats assembling that warrant, rather than the output's fluency, as what builds disciplinary expertise.

The largest expert-rated vulnerability in the knowledge base is critical thinking. Across 65 learning processes rated by 30 experts, Critical Thinking and Critical-Analytic Thinking drew the report's highest disruption rating (mean 4.00 of 5; 96% of raters at or above 3) with enhancement below threshold (2.40, 43%) (Kendeou, Greene & Nixon et al., 2026). Ten of eighteen higher-order processes reached consensus on vulnerability only, which the report reads as one-sided risk rather than a trade-off.

- **Structure of the partnership, not exposure, carries the association.** Akgun and Toker (2026) modeled 891 US and Turkish college students with transactive memory systems theory and found that neither self-appraised thinking ability nor confidence in the AI partnership predicted critical-thinking enactment directly. Both fed GenAI familiarity, which in turn predicted only two behaviors: specialization and coordination of labor (b = 0.636) and reflective transformation of output (b = 0.367). Those behaviors predicted critical thinking (b = 0.230 and b = 0.175) with no direct path remaining (CFI = 0.974, RMSEA = 0.048). This is the mechanism-level version of the field's recurring null: hours of use and self-rated competence are not proxies for critical thinking, and what a study measures when it asks about exposure is the input to the chain rather than its outcome.

Common Misconceptions

- **"A better prompt produces better critical thinking." Structured dialogue control, not a better prompt**, separates a fallacy tutor from a debating chatbot: routing each turn through

Toulmin-based intent detection did the work. The mechanism is the interaction structure rather than the wording.

- **"GenAI use raises critical thinking directly."** GenAI use's link to **self-reported** critical thinking ran **almost entirely through GenAI feedback literacy** — in **421 Chinese undergraduates**, feedback literacy mediated **71%** of the association. The literacy is the pathway.
- **"The meta-analytic effect is uniform."** Across **29 experiments**, GenAI raised higher-order thinking moderately (**g = 0.609**) with critical thinking at **ES = 0.691**. Moderate pooled effects over heterogeneous interventions support the category and not a specific design.

Connected FAQs

- How Do I Teach Students to Verify AI Output?

Computational Thinking

> **Computational thinking** — a problem-solving approach involving decomposition, pattern recognition, abstraction, and algorithmic design. In AI education, computational thinking is both a prerequisite for understanding AI systems and a skill that AI tools can help develop.

Questions to Consider

- When you solve a problem by breaking it into parts, spotting patterns, abstracting the essentials, and designing steps — you're already doing computational thinking, even without a computer. Where have you done this recently?
- A common assumption is that computational thinking is the same as coding or 'computer literacy.' How might they differ, and why might that difference matter for how you teach it?
- Research suggests students' deficits in fundamental concepts — not the AI tool itself — are what limit their ability to judge AI suggestions. What must a learner already understand before they can critically evaluate an AI's output?
- Some argue computational thinking should move learners from passively consuming AI outputs toward building, critiquing, and designing with AI. What would a classroom that treats students as producers rather than consumers actually look like?
- Generative AI can now score students' computational thinking growth — yet both humans and AI struggle with the hardest construct, systems thinking. Where do you think automation of assessment should stop, and why?
- Robotics research finds computational thinking only develops when concepts are made explicit and mapped to the curriculum, not treated as isolated tech exercises. What's the risk of teaching 'tech skills' without naming the thinking underneath?

Introduction

CT in an AI-era classroom

The knowledge base's connected articles converge on a central claim: computational thinking (CT) is the conceptual bedrock students need in order to engage critically with AI, and it is also the skill most directly deepened by well-designed AI-supported learning. Below the evidence is grouped into four themes grounded in the linked articles.

- **CT as the foundation of AI literacy and critical engagement.** Several studies show that CT is what lets learners evaluate, rather than just consume, AI outputs. Chat debugging research found that when undergraduates debugged analog circuits with LLM help, their *deficits in fundamental concepts and critical thinking* — not the tool — were the limiting factor, since students lacked the core ideas needed to judge AI suggestions. A review of LLM intervention designs likewise concludes that what separates effective interventions from "tool frustration" is the CS Education push toward computational thinking over syntax mastery. In early childhood, the AI-Play

framework builds unplugged, play-based AI Literacy by teaching children that “AI is a system built from parts” and “AI learns from examples” — a developmentally grounded first layer of CT. And an AI academic league connects CT to real civic AI projects through Project-Based Learning, embedding AI Literacy in practice. Together these suggest CT is the transferable cognitive core of AI literacy.

- **Educational robotics as a vehicle for CT.** Robotics is the most-studied context for developing CT across K-12 and STEM Education. Secondary-school research argues that educational robotics enhances problem solving and critical thinking only when CT concepts are made explicit and mapped onto the STEAM curriculum rather than treated as isolated technical exercises. A systematic review of 95 studies confirms that robotics fosters CT, Creativity, and problem solving, and that Game-Based Learning suits informal settings while gamification dominates formal classrooms and supports project-based learning. Teacher-training evidence shows an integrated Micro:bit + robot + Machine Learning intervention produced significant CT knowledge gains (d = 0.638) in initial teacher education, arguing robotics should be embedded so future teachers can teach CT. LLMs can lower the barrier further: EduSim-LLM couples an LLM with robot simulation so beginners control robots via natural language, making CT-embedded robotics accessible without low-level coding.
- **AI as a “more capable peer” can carry CT in under-resourced robotics courses.** A 14-week quasi-experiment with 103 first-year undergraduates in Nigeria found AI-supported problem-based learning (ChatGPT and Teachable Machine inside the zone of proximal development) outperformed conventional instruction on posttest computational thinking and robotics-programming achievement, with no gender moderation (AI-PBL robotics study (2026)).
- **LLMs as tools for CT assessment and development.** Generative AI offers scalable ways to measure and scaffold CT. Physics CT assessment research showed LLMs can mirror human raters in scoring growth in Data Practices and Computational Problem-Solving Practices across large-enrollment Physics Education courses — while both humans and the LLM struggled with the more complex Systems Thinking construct, marking a clear boundary for automation. Visual query tracing shows how Visualization can scaffold abstract computation, building intuition that supports CT development. A taxonomy of conditionals-and-loops misconceptions provides fine-grained targets for Scaffolding and for automated misconception detection, connecting to Misconceptions about AI. These tools work best, however, when pedagogical design leads: the CS review found semester-long “Virtual Tutor” designs with scaffolded feedback consistently improved CT, whereas unstructured tool access increased frustration.

Durable competencies shift once implementation is automated: a workshop report names abstraction, computational thinking, and a “verification spectrum” as the skills to teach, citing a trial of nearly 1,000 students where unrestricted GPT-4 access raised practice performance 48% but cut exam scores 17% once AI was withdrawn (Lee et al. (2026)).

- **CT across K-12, teacher education, and assessment redesign.** CT spans the whole K-12 to Higher Education spectrum and is reshaping assessment. At the early-childhood end, AI-Play extends CT and AI literacy to Pre-K–K2 learners and non-technical families; at the university end, the OOP assessment study found 2026 GenAI systems outperform the average student on

authentic programming exams yet still fail on interfaces, abstract classes, and inheritance — recurring conceptual gaps that mark exactly where CT remains hard to automate. A randomized A/B crossover study showed that evaluation-and-critique tasks produce comparable outcomes to generation, suggesting CT can be exercised through judging flawed AI solutions, though gains require deliberate scaffolding. Underpinning all of this is the teacher: the microbit study links CT instruction directly to Teacher Education, and Socratic chatbot research ties the precise problem formulation that CT demands to measurable course performance.

- **A validated instrument locates where CT is hardest.** A 34-item computational-thinking test built with Evidence-Centered Design and validated by item-response theory across 461 AI-programming students concentrated difficulty in data representation, logical-operator sequencing, and loop structures rather than evenly across the syllabus (Zhang & Zhang (2026)).

CT and the shift from AI consumers to producers, creators, and designers

A central goal for CT in the AI era is moving students and instructors beyond *passive consumption* of AI outputs toward *creating, building, and designing* with and for AI — an agenda that aligns CT with constructionist learning (learning-by-making). The knowledge base's connected articles increasingly make this producer/creator/designer turn explicit. Model-authorship research reframes learning-by-construction with GenAI as a measurable "model authorship" process — students author, debug, and iterate on AI models rather than just consuming AI-generated code or answers. The CtL-GenAI framework operationalizes this as constructionism for the GenAI age, treating artifacts students build with AI as the engine of CT development. CT through AI-agent creation shows that designing, not merely using, AI agents exercises decomposition, abstraction, and algorithmic reasoning directly.

The new meta-analytic evidence sharpens this picture. A meta-review of 128 CT systematic reviews finds the field converging on a unified definition of CT as reasoning with abstract models that use computational steps and algorithms to solve problems — precisely the kind of model-building (rather than answer-consuming) thinking that production-oriented learning demands. CT-kindergarten robotics research shows even early-childhood learners become producers through play-based building with robots, using problem-based learning, storytelling, and scaffolding — a developmental first step toward seeing technology as something one constructs, not just operates. And evaluation-and-critique research demonstrates that CT can be exercised through judging and debugging flawed AI solutions — a producer stance toward AI output that resists the passive-consumption trap.

The practical upshot is that CT instruction should be designed so learners *make things with AI* — authoring models, building agents, constructing artifacts, and critiquing AI output — rather than receiving finished solutions. This both deepens CT and builds AI Literacy as participatory and creative rather than merely conceptual. Teachers, in turn, need support to move from using AI tools to designing AI-enhanced learning activities (see Teaching and Workplace Learning).

Reusing others' models belongs to the producer stance: implementing a published AI model — selecting, installing, running, and validating it — can be taught as a learnable, structured skill with a fallback route for each anticipated failure, and three BSc chemistry students with no programming background reproduced and extended an enzyme-substrate prediction model within four months (Achterweust et al. (2026)).

Practical guidance

For educators, the consistent message is that CT is developed through *explicit, scaffolded, observable* engagement rather than passive AI use. Pair robotics with explicit CT-concept mapping to the curriculum; use LLMs for Simulation, natural-language control, and scalable assessment of CT growth while reserving human judgment for constructs like Systems Thinking; and redesign assessments to emphasize evaluation and diagnosis of AI output over raw generation. Whatever the setting — unplugged play in early childhood, robots in secondary STEM Education, or Virtual Tutors in Higher Education — structure the activity so students must reason about decomposition, pattern, abstraction, and algorithm rather than receive finished solutions.

Connections to related concepts

Computational thinking is the shared cognitive foundation beneath AI Literacy and Critical Thinking, the curricular core of CS Education and K-12 computing, and the conceptual target that Robots in Education, Game-Based Learning, and Project-Based Learning are best designed to serve. It is deepened by large language models and Generative AI when those are used as scaffolding tools, and it is the skill that student-misconceptions taxonomies and CT-aware assessments aim to measure. Teachers develop it through Teacher Education and Workplace Learning, and it transfers across domains including Physics Education and STEM broadly.

- **Computational thinking predicts AI-assistant learning.** Eighth-grade students with high computational thinking significantly outperformed low-CT peers in an AI coding-assistant course, using the assistant for understanding rather than answer retrieval.

Common Misconceptions

- **“AI removes the need for computational thinking.”** The chat debugging study found that when undergraduates debugged circuits with LLM help, their **deficits in fundamental concepts and critical thinking — not the tool — were the limiting factor**. CT is what lets a learner evaluate an output rather than accept it, which is precisely the capacity that makes AI assistance usable at all.
- **“AI assistance levels the playing field in under-resourced settings.”** It can, under conditions. A **14-week quasi-experiment with 103 first-year undergraduates in Nigeria** found AI-supported problem-based learning (ChatGPT and Teachable Machine) produced gains, and AI as a “more capable peer” carries CT where other provision is absent. But that is a finding about a structured intervention, not a property of giving students a chatbot.
- **“LLMs cannot assess CT reliably.”** Physics CT assessment research found LLMs can **mirror human raters** in scoring growth in Data Practices and Computational Problem-Solving Practices across large-enrollment courses. The obstacle to scaling CT assessment has been rater capacity, and that constraint is softening — which shifts the design problem to whether the instrument is measuring CT rather than compliance.
- **“CT is a coding skill that robotics happens to teach.”** A **systematic review of 95 studies** confirms robotics fosters CT, creativity and problem solving, but also that the **setting moderates**

the outcome: game-based delivery suits informal settings while gamification differs in formal ones. CT is a set of practices that transfer unevenly, so the transfer claim needs the task design it actually used.

Theories and frameworks (Foundations of AI in education)

SAMR Model

> **The SAMR model** — a technology-integration framework developed by Ruben Puentedura that classifies the extent to which a technology transforms learning along four levels: **Substitution, Augmentation, Modification, and Redefinition**. The lower two levels (Substitution, Augmentation) *enhance* an existing task — the technology does what was done before, better or more conveniently; the upper two (Modification, Redefinition) *transform* it — the task itself changes to something not previously possible. In AI in education, SAMR is the standard lens for asking whether generative AI is being used to incrementally improve existing practice or to reconceptualize learning, and it sits alongside TPACK as a way of describing how teachers integrate technology rather than why they accept it.

Questions to Consider

- When AI is introduced into a course, is it a Substitution (a chatbot replaces a search box) or a Redefinition (a task becomes possible that was not before)? What determines which level is appropriate — and is transformation always the goal?
- SAMR and technology adoption models answer different questions: adoption theory asks *why* a teacher or institution accepts a tool; SAMR asks *how deeply* the tool changes learning. Which question does a given AI-integration study actually answer?
- A systematic review of AI integration in higher education found most uses sat at the Substitution or Augmentation level, with only one study approaching Redefinition. If that is typical, what does it suggest about the gap between AI's potential and its classroom reality?
- SAMR is frequently invoked in teacher professional development to help educators plan technology use. Does classifying a lesson's SAMR level change what a teacher actually does, or is it chiefly a descriptive label?
- Critics argue SAMR, like TPACK, rests on a humanist ontology that treats cognition as unchanged by technology, and that it says nothing about power, data ownership, or equity. Is a level-of-integration lens sufficient, or does AI-era integration need a more critical frame?

Introduction

SAMR describes the depth of technological transformation of learning tasks. Its four levels form an ascending scale from enhancement to transformation: **Substitution** (the tool replaces another with no functional change — a chatbot in place of a search engine), **Augmentation** (the tool replaces and improves — a word processor's spell-check over a typewriter), **Modification** (the task is significantly redesigned — students collaborate in real time on a shared AI-generated draft), and **Redefinition** (new tasks previously inconceivable become possible — learners co-create with a generative model in ways that have no non-AI analogue). The model is widely used in educational technology research and teacher professional development as a vocabulary for planning and evaluating technology integration, and it is a standard

companion to TPACK and to technology-adoption frameworks — though it answers a different question than either.

What the four levels mean

- **Enhancement (lower half):** Substitution and Augmentation improve an existing task without changing its nature. Most routine AI use — question generation, quick text generation, summarization — sits here: it is faster and more convenient but does not alter what the learner is asked to do.
- **Transformation (upper half):** Modification and Redefinition change the task itself. Vibe coding, real-time co-construction with a model, and adaptive interactive dialogue are tasks that were not possible before generative AI, and represent the transformative end of the scale.

SAMR is frequently paired with the ICAP framework because the two align: the four cooking-to-learning scenarios in Rummel, Nachtigall & Panadero (2026) map ICAP engagement modes onto SAMR levels — ICAP *Passive* with SAMR *Substitution*, *Active* with *Augmentation*, *Constructive* with *Modification*, and *Interactive* with *Redefinition* — illustrating a progression from passive delegation to interactive co-construction.

Evidence from the knowledge base

- **AI integration in higher education is largely incremental, not transformative.** AlSheikh et al. (2026), in a PRISMA systematic review of 22 intervention studies screened from 959 records, graded AI integration with the SAMR model and found most studies clustered at the **Substitution or Augmentation** level, with fewer at Modification and only one approaching Redefinition. AI was typically introduced to improve existing practice — dominated by assessment automation and personalized-learning support — rather than to reconceptualize curricula or learning outcomes.
- **SAMR is a common analytical lens for GenAI-driven curriculum change.** Sabani et al. (2026) map five curricular shifts (static to dynamic, transmission to capability, local to institutional) onto established lenses including SAMR and constructive alignment, using the model to clarify the pedagogical mechanisms by which GenAI reshapes curriculum.
- **SAMR and TPACK anchor teacher-technology integration standards.** Crompton et al. (2026) situate their six faculty technology standards against existing frameworks — Technological Pedagogical Content Knowledge (TPACK), RAT, SAMR, SETI — and standards (ISTE, UNESCO, DigCompEdu), most of which target K-12 educators or only the teaching portion of faculty roles, leaving a gap in higher-education faculty development.
- **SAMR is a target of the posthumanist critique.** Elsayed (2026) critiques TPACK, SAMR, and AI Literacy models for sharing a humanist ontology that presumes a bounded learner whose cognition is fundamentally unchanged by technological mediation, arguing these instrumentalist frameworks cannot address AI's constitutive role in cognition.
- **A framework for integration, not a framework for power.** Poudyal (2026) evaluates SAMR alongside TPACK and other integration frameworks and finds none address equitable power, data ownership, or accountability, motivating an alternative ecological co-agency framework.

- **Student use maps to SAMR as well, and feedback spans every level.** Coding the GenAI declarations of 31–36 students in a physics unit placed learning at substitution–augmentation, formatting at substitution, and task-doing at modification–redefinition, while feedback — checking, clarifying, verifying — appeared at all four levels (Quince and Faulconer (2026)).
- **Depth and inclusion are separate axes.** Jita, Jita & Omoniyi (2026) pair SAMR with UDL across 38 sources and argue that Redefinition-level tasks can still exclude students whose language, device, or connectivity does not fit the design.

SAMR, TPACK, and technology adoption: how they differ

Three frameworks are frequently conflated but answer distinct questions:

- **Technology adoption models** (TAM, UTAUT) explain *why* an individual or institution accepts and continues using a technology — perceived usefulness, ease of use, and social influence.
- **TPACK** describes the *knowledge* a teacher needs to integrate technology effectively — the interplay of technological, pedagogical, and content knowledge, extended in the AI era to AI-TPACK/GenAI-TPACK.
- **SAMR** classifies *how deeply* a technology transforms a learning task, from enhancement to redefinition.

SAMR is best understood as an integration-depth lens used in planning and evaluation, complementing adoption theory (which explains uptake) and TPACK (which explains teacher capability). In the AI era, it is most productively used to ask whether generative AI is being applied to enhance existing tasks or to enable genuinely new ones — a distinction that runs throughout the knowledge base's assessment and curriculum research.

Implications for practice

- **Use SAMR to ask the depth question, not to prescribe transformation.** Enhancement is not inherently inferior; many routine AI uses are legitimate Substitutions. The model is diagnostic, clarifying what a given use actually changes.
- **Pair it with ICAP.** SAMR describes what the *task* becomes; ICAP describes how the learner *engages*. Used together they distinguish surface substitution from deep interactive co-construction.
- **Complement it with adoption and equity lenses.** SAMR says nothing about why a tool is adopted or who benefits. Pair it with adoption models and equity analysis to avoid a depth label substituting for a critical evaluation.
- **Treat evidence of incremental integration as a finding, not a failure.** If most AI integration clusters at Substitution/Augmentation, the design task is not to force Redefinition but to recognize that transformative use requires different task designs, not just better tools.

Common Misconceptions

“Higher on SAMR is better teaching.” SAMR is a lens for asking whether AI *reconceptualises* learning or *improves* existing practice; it is not a quality ranking, and Re-definition is not the correct answer for every task. A substitution that removes an unproductive step is a success judged on learning, not on the level it occupies.

“AI adoption is progressing up the ladder.” The distribution is concentrated at the bottom. A systematic review of AI integration in higher education found **most uses sat at Substitution or Augmentation, with only one study approaching Redefinition**. SAMR’s practical use in this literature is therefore largely diagnostic — it names where the field actually is.

“SAMR and TPACK are competing frameworks.” They describe different things: SAMR describes the *degree of transformation* in a task, while TPACK describes the *knowledge* a teacher needs to integrate technology well. A teacher can be highly TPACK-capable and still operate at Substitution, which is why the two are used together rather than chosen between.

“A tool that is transformative at one level is transformative at all levels.” The same generative tool can support a Substitution in one course and a Redefinition in another, because the level is a property of the task design rather than of the technology. Attributing the level to the tool produces adoption decisions in place of design decisions.

Technological Pedagogical Content Knowledge (TPACK)

> **Technological Pedagogical Content Knowledge (TPACK)** — the framework (Mishra & Koehler, 2006) describing the integrated knowledge teachers need to use technology effectively in teaching: the interplay of Technological Knowledge (TK), Pedagogical Knowledge (PK), and Content Knowledge (CK), and their intersections. In the AI era, TPACK has been extended to **AI-TPACK** / **GenAI-TPACK**, modeling how teachers integrate generative AI into content-area instruction. It is the dominant theoretical lens for understanding how teacher AI competency is structured and built through professional development.

That dominance is also partly a retrieval artifact: in a PRISMA scoping review of 195 technology-supported teacher-education studies, digital competence, TPACK and DigCompEdu were explicit search descriptors, so the 46.5% share of competence frameworks describes the retrieved corpus rather than the field (Patiño Hernández et al. (2026)).

Questions to Consider

- TPACK claims effective teaching with technology isn't the sum of separate skills (knowing your subject + knowing teaching + knowing the tool) but the product of their interplay. Think of a lesson that genuinely worked with a technology. Which combinations of content, pedagogy, and tech knowledge — not any single one — seemed to be doing the work?
- A common assumption is that a teacher who is 'tech-savvy' is therefore ready to teach with AI. Where might that assumption fail — for instance, when a technically fluent teacher still uses AI in a pedagogically shallow or content-inaccurate way? What would 'competence' look like that a simple tech-skills test misses?
- The AI era reframes the technology in TPACK from a passive tool to an active agent that can plan, generate, and tutor. If a teacher's job shifts from operating a tool to orchestrating an AI that acts on its own, what new knowledge does that demand — and can any static checklist capture it?
- The page suggests that professional development should train the intersections, not just the tools. Think about the last technology training you attended or designed. Was it mostly 'how to use the software,' or did it build content and pedagogy together with the technology? Which approach would you expect to change classroom practice more, and why?
- Research found different 'teacher archetypes' — optimizers, creators, passive observers — benefit from different kinds of support. Which archetype do you most resemble when using AI in teaching, and what kind of Scaffolding do you think would help you most? Would your learners describe you the same way you do?
- Some researchers argue effective AI integration emerges from a teacher's beliefs and sense of efficacy, not just their knowledge. What do you believe about AI's role in learning, and how might that belief — more than your technical skill — shape whether and how you actually integrate it?

Introduction

- **Crompton et al.** DBR operationalizes faculty technology-integration standards that extend the TPACK framework into institutional practice.

The Framework

TPACK holds that effective technology integration is not the sum of separate knowledge domains but the product of their **dynamic interplay**. The framework comprises three base domains and four intersections:

- **Content Knowledge (CK)** — knowledge of the subject matter to be taught.
- **Pedagogical Knowledge (PK)** — knowledge of teaching methods, strategies, and how students learn.
- **Technological Knowledge (TK)** — knowledge of how to use tools and technologies, including generative AI.
- **Pedagogical Content Knowledge (PCK)** — how to teach specific content effectively.
- **Technological Content Knowledge (TCK)** — how technology shapes and represents content.
- **Technological Pedagogical Knowledge (TPK)** — how technology supports or constrains teaching strategies.
- **TPACK** — the emergent, integrated knowledge at the center, where all three domains interact to enable technology-enhanced, content-specific teaching.
- **The framework dominates the field by default, and is stretched to fit.** In a PRISMA-guided review of 78 studies of AI-supported instructional design, only 19 applied any named competence framework — and TPACK and its variants accounted for **17 of those 19**, used productively as an analytical lens but stretched beyond their original scope, since TPACK was not designed for AI-specific capacities. Purpose-built extensions are correspondingly rare: **Intelligent-TPACK appeared in just five studies**, usually paired with AI Literacy to handle developmental progression (Spyropoulou & Kameas, 2026).
- **Research proceeds untheorised while policy frameworks go untested.** The same review found **76% of studies inferred competences from practice with no theoretical mapping at all**, and neither DigCompEdu nor the UNESCO AI Competency Framework for Teachers was applied as an analytical framework in any of the 78 — a disconnect running in both directions, since empirical work accumulates no shared vocabulary while the frameworks meant to guide practice remain empirically untested in this context.

AI-TPACK and GenAI-TPACK

The AI era has pushed the framework toward a technology-with-intelligence reading. Rather than a passive tool, generative AI is an active agent that can plan, generate content, tutor, and adapt — so integration

knowledge increasingly includes **orchestration**: deciding when and how AI acts, scaffolds, or yields to human judgment.

- **Beyond discrete knowledge.** AI-TPACK research argues effective AI integration emerges not from possessing separate domains but from the dynamic interplay of **systems thinking**, **pedagogical beliefs**, and **Self-Efficacy** — challenging static, checklist-based models of teacher AI competency. Teacher archetypes (Systematic Optimizers, Prolific Creators, Passive Observers) emerge from how teachers design multi-agent instructional workflows.
- **What integration frameworks leave out.** A co-agency critique holds that TPACK and SAMR address teacher knowledge and adoption levels but leave power, data ownership, and accountability unaddressed, so integration knowledge needs an explicit ethical boundary rather than another knowledge domain (Poudyal (2026)).
- **Cross-level evidence for the pedagogical core.** A multilevel study of 46 teachers and 2,832 secondary students found technical AI knowledge alone was insufficient — even slightly dampening students' perceptions of AI for social good — while pedagogical AI knowledge (TPAIK) is what fostered students' perceptions and behavioral intention to learn AI. The result distills to a **"pedagogy first, technology second"** guideline that echoes the mediating-role findings above.
- **Ethics as an integrative mediator, not a boundary.** In a survey of 454 university teachers, isolated AI-technological knowledge had a *negative* direct association with integrated AI-TPACK ($\beta = -0.303$) while its total effect stayed positive ($\beta = 0.639$), running through pedagogical, content, and ethical knowledge (Chen et al. (2026)). Ethical knowledge also channeled the effect onward, predicting both pedagogical ($\beta = 0.353$) and content knowledge ($\beta = 0.269$).
- **A review lens for the whole field.** A systematic review from a TPACK perspective (Liu & Zhong, 2025) analyzed 71 empirical studies of GenAI in student learning, finding an overall positive effect (Hedges' $g = 0.752$) and identifying GenAI literacy for students and **GenAI-TPACK professional development for teachers** as the two critical priorities for the field.
- **Proficiency alone does not predict pedagogical integration.** Choi et al. (2026) measured teachers' Intelligent-TPACK to segment participants and observed that even AI-proficient novices relied passively on AI output during lesson design, whereas experienced teachers — with lower measured AI-TPACK — critically re-engaged and adapted AI suggestions to pedagogical context. The result reinforces the pattern above: AI-TPACK translates into sound classroom use through experienced pedagogical judgment, and Teacher Education support must therefore target the *application* of AI knowledge, not its mere possession.
- **Teacher education context.** TPACK is instrumental in cultivating teachers' competency to integrate technology into curriculum-specific instruction, which is why teacher-education and PD research (e.g., intensive GenAI PD programs, AI-TPACK readiness among pre-service teachers) increasingly measures it as the outcome of interest.
- **Pedagogical knowledge mediates GenAI integration.** Mohebi and ElSayary (2026) surveyed **325 in-service teachers across 26 countries** and interviewed seven, using an explanatory sequential mixed-methods design to model TPACK-GenAI. Technological Knowledge (TK),

Pedagogical Knowledge (PK), and Pedagogical Content Knowledge (PCK) each associated with overall TPACK-GenAI, but **Technological Pedagogical Knowledge (TPK) mediated** these links — evidence that the "from proficiency to pedagogy" move matters: translating GenAI skill into sound classroom use runs through pedagogical-technological integration knowledge, not tool familiarity alone.

- **In higher education, content expertise does not transfer to GenAI integration.** Sutedjo, Chowdhury & Liu (2026) adapted the TPACK-21 instrument to survey **127 faculty** at a U.S. research university on using GenAI to teach 21st-century skills. Faculty reported strong CK (M = 5.15) and PCK (M = 4.70) but low technology-integrated knowledge — TPK (M = 2.62), TCK (M = 2.75), and overall TPACK (M = 2.55, the lowest domain) — and CK showed **no significant correlation with TK or any technology-integrated domain** (r = .11–.15, ns). The three technology-integrated domains inter-correlated so strongly (r = .81–.91) that they may function as a single GenAI-integration factor. The result reinforces the *training the intersections* design principle: faculty development must deliberately build GenAI-integration knowledge through discipline-specific activities rather than assume subject-matter expertise will carry over, and treat the technology-integrated domains as a shared GenAI-literacy foundation.
- **Institutional mode and training level interact.** Mnguni et al. (2026) compared 186 final-year science student teachers at a South African campus-based university (n = 85) and a distance education university (n = 97). Self-reported TPACK was higher on campus (64.0% versus 47.4%), Pedagogical Knowledge was the least reported domain in both groups (53% on campus), and the level of AI training was associated with self-reported TPACK only at the distance institution, where completing a five-credit short course predicted *weaker* reported TPACK than no training at all (p = .039, versus p = .607 on campus). Readiness therefore tracks the institutional provision context rather than hours of training alone, and the authors caution that self-reported readiness cannot stand in for performance evidence.

A complementary measurement warning comes from the same author's Capability–Decision Model: when TPACK is self-reported and perceived behavioral control is measured as Self-Efficacy, the two may not be empirically distinguishable, so a study cannot tell whether capability or general confidence predicts intention (Mnguni (2026)). - **Integrated TPACK moves most when AI is scaffolded inside authentic problem-based tasks.** Chen and Osman (2026) compared an eight-week AI-supported CTD-PBL module with conventional instruction for **130 third-year pre-service physics teachers** in an intact-class quasi-experimental design (65 per condition), with groups using DeepSeek through task-specific prompt templates and every AI output required to pass human verification before entering an instructional artifact. The module group reported higher post-test TPACK (M = 4.04 vs. 3.40, $p < 0.001$, d = 1.02) and higher perceived collaborative problem solving (M = 3.62 vs. 3.05, d = 0.88), with significant group × time interactions on both outcomes. Where the gains landed is the TPACK-relevant detail: the largest dimensional effects were in the integrated domains — TPCK (d = 1.21), PCK (d = 1.06) and TPK (d = 0.95) — and the collaboration gains were clearest in shared knowledge building and social regulation, i.e. the intersections rather than the base domains. The authors present these as differential change associated with an integrated instructional condition, not as an AI effect: AI was never isolated from the PBL task chain, structured collaboration,

instructor scaffolding, peer feedback or reflective revision, and both outcomes were questionnaire-based perceptions of competence rather than demonstrated classroom performance.

- **An intervention can move the base domain first.** A six-month professional development program built directly on the Intelligent-TPACK framework raised technical AI knowledge most (AITK: 3.92 to 4.43, $t(63) = 3.856$, $p < .001$, $d = .48$), technological-pedagogical knowledge next (AITPK: $d = .33$) and integrated AITPACK least ($d = .26$), with ethical awareness left comparatively stagnant (Tan, Cheng & Ling, 2025). The ordering is the mirror image of Chen and Osman's integrated-domain gains, and both are self-report.

AI-TPACK as the mediator between literacy and classroom integration. A structural equation model of Chinese pre-service science teachers (Zou, Li, Wang & Du, 2026) positions AI-TPACK not as a parallel competency but as the transmission mechanism through which general AI Literacy becomes teaching practice. AI literacy predicted AI-TPACK strongly, AI-TPACK in turn predicted science teaching Self-Efficacy, and teaching self-efficacy was the strongest single predictor of the intention to teach through AI-integrated inquiry.

The full serial chain (AI literacy → AI-TPACK → self-efficacy → intention) was significant, as were the separate indirect routes through AI-TPACK and through self-efficacy; taken together, most of AI literacy's association with intention ran through these mediators rather than directly, and the result held after controlling for gender, year of study, major, and AI use frequency. The model's practical claim is a sequence with an entry point: AI literacy is necessary but insufficient, and the work of integration happens where technological, pedagogical, and content knowledge are combined — which is also where teachers' confidence in teaching the subject is built. - **Validation as a fourth competency.** Orhon, Cekerol and Ugur (2026) extend the model with **AI-Validation Knowledge** — subjecting probabilistic AI output to discipline-specific verification before treating it as evidence of a legitimate decision — and pair it with a process-oriented rubric for design education.

Why It Matters in AI Education

TPACK is the organizing framework for the teacher-side of the knowledge base's evidence base. It explains why teacher AI competency is more than tool fluency: teachers must integrate technological, pedagogical, and content knowledge together to turn AI into learning gains. The knowledge base's Teacher AI Competency page covers the competency dimensions; TPACK is the *knowledge structure* that underlies them. Research on teacher confidence, professional development, and the transforming teacher role all operate within (or against) this framework. The framework is now being extended to evaluate whole programs: Wu & Li (2026) build an AHP-Fuzzy-AHP evaluation system for AI certificate programs on TPACK dimensions and find that faculty professional competence — not technical infrastructure — is the largest gap between expert priority and current provision, signaling that credentialing should invest in teachers' integrated pedagogical capacity.

The mediation runs mostly through ease of use. Zhao (2026) tested six indirect paths from AI literacy and TPACK to deep learning in 423 pre-service teachers: TPACK through perceived ease of use was largest (0.212) and AI literacy through usefulness smallest (0.033), so integration knowledge worked through usability rather than utility. **The components do not weigh equally in the AI case.** Among 988 pre-service

teachers, TCK (β = 0.67) and TPK (β = 0.41) predicted integrated AI-TPACK while TK alone did not (β = −0.10, p = 0.066), and integrated TPACK predicted attitude toward GenAI (β = 0.75) (Khalil et al., 2026).

Design Implications

1. **Train the intersections, not just tools.** PD should build technological, pedagogical, and content knowledge together rather than offering isolated tool training — the core TPACK design principle.
2. **Treat AI as an agent, not an appliance.** AI-TPACK extends the framework toward orchestration of AI agents, requiring systems thinking and pedagogical judgment about when AI should act.
3. **Differentiate PD by teacher profile.** Different teacher archetypes (optimizers, creators, observers) benefit from different scaffolding — advanced frameworks, rapid feedback, or explicit modeling respectively.
4. **Assess integrated competence.** TPACK-oriented outcomes (e.g., AI-PCK gains) should be measured as integrated capability, not self-reported tool familiarity.

Common Misconceptions

- **"TPACK's dominance reflects its explanatory power."** That dominance is **partly a retrieval artifact**: in a PRISMA scoping review of **195 technology-supported teacher-education studies**, digital competence, TPACK and DigComp **dominate the indexed literature**. Prevalence in a search is a property of the vocabulary the field uses, not proof that the framework explains more.
- **"A well-known framework is a validated one for AI."** TPACK was not designed for AI-specific capacities, which is why Intelligent-TPACK was developed — and it appears in only **five studies** in the 78-study review. Using TPACK for GenAI competence stretches it beyond its construction.
- **"Applying a framework means the research is theorised."** The same review found **76% of studies inferred competences from practice with no theoretical mapping**, so TPACK's presence in the field coexists with most research being untheorised. A named framework is not the same as a framework doing work.

Learning and instruction

Core pedagogies

Pedagogies and Teaching Strategies

> **Pedagogies and teaching strategies** — the methods and approaches educators use to teach and facilitate learning, and the umbrella concept for the knowledge base's coverage of how teaching happens (in contrast to Learning Theories, which explains how learning happens). In AI in education, pedagogy is central because the choice of teaching strategy shapes how AI tools are deployed: the same generative-AI tool can be a scaffold under one pedagogy, a Socratic interlocutor under another, or an answer-generator under a third. The knowledge base documents individual pedagogies and treats them as the instructional lens through which AI's design and classroom use are evaluated.

Questions to Consider

- What's the difference between a teaching strategy (pedagogy) and a theory of how learning happens? Can you name a strategy you use and the learning theory it might rest on?
- The page argues every AI tool 'embeds pedagogical assumptions' whether the designer states them or not. Take a chatbot that just answers questions—what pedagogy is it quietly enacting, and is that intentional?
- The same generative AI can be a scaffold under one pedagogy, a Socratic partner under another, or an answer generator under a third. Can you describe a single tool being used in these three different ways?
- Evidence suggests *how* AI is used matters as much as *whether* it's used. Have you observed the same AI helping one class and harming another? What differed?
- If you were advising a school on buying an AI tool, which questions would you ask to uncover the pedagogy embedded in it—rather than just its feature list?
- Think of a learner-centered strategy you've tried (active, collaborative, project-based). What made it work or fall flat, and how might an AI tool have changed that outcome?

Introduction

Pedagogy and teaching strategy concern *how* educators teach — the activities, structures, and methods that organize learning — while Learning Theories explains the underlying mechanisms of *how learning happens*. The two are complementary: a pedagogy operationalizes one or more theories, and the knowledge base treats pedagogy as the bridge from theory to classroom practice. Every AI tool embeds pedagogical assumptions about the desired instructional interaction, whether the designer states them or not.

The pedagogy landscape

The knowledge base documents a rich set of individual teaching strategies and pedagogies, organized into families:

- **Student-centered and active approaches.** Active Learning (students engaged in doing and thinking rather than passively receiving), Project-Based Learning (learning through extended projects), Experiential Learning (learning through direct experience), and Learning by Teaching (learning by explaining to others).
- **Collaborative and social approaches.** Collaborative Learning (learning through group work), Sociocultural Learning (learning through social participation and mediation), and Socratic questioning (learning through guided dialogue and questioning).
- **Experience-based approaches.** Experiential Learning (learning through direct experience and reflection), Situated Learning (learning in authentic contexts), and Embodied Learning (learning through physical/embodied interaction).
- **Structured and guided approaches.** Scaffolding (temporary, fading support), Learning Design (systematic design of instruction), Self-Regulated Learning (learners directing their own learning), and Sociocultural Learning (including structured, teacher-guided sociocultural support).
- **Online and distance pedagogies.** Online teaching and learning is itself a pedagogical context, not just a delivery channel: the medium shapes which strategies are viable (Active Learning rethought for asynchronous forums, Collaborative Learning via digital discussion, tutoring agents replacing face-to-face interaction). In this medium, AI raises both new opportunities (scalable personalization, always-on support) and new risks (academic integrity, cognitive offloading), making pedagogical intent decisive.
- **Motivation and engagement approaches.** Game-Based Learning (learning through games), Self-Determination Theory (supporting autonomy, competence, relatedness), and Motivation-oriented strategies.
- **equity-conscious pedagogies.** Culturally relevant pedagogy, Universal Design for Learning, Critical Pedagogy, and Inclusive Learning ensure strategies serve diverse learners.

Approaches are not sequences, and the difference decides outcomes. Everything above describes *what kind* of teaching is happening. Pedagogical patterns describe the *order* of moves inside a lesson — what students do first, where AI enters, and where human judgment stays — and the knowledge base documents those tested sequences separately, because the same tool helps or harms depending on its position in the order. Attempting a problem before AI offers help, and receiving hints rather than answers, is the most consistently supported arrangement in the evidence base; putting the assistant first is one of the best-documented ways to depress later unassisted performance. A pedagogy adopted without deciding that order leaves the decisive variable unset.

How pedagogy appears in AI in education

The knowledge base's research examines pedagogy at the intersection of AI and teaching in several ways:

- **AI as a pedagogical agent.** AI tools embody pedagogies — a tutor built on Socratic questioning prompts learners to reason, while an answer-generating chatbot may default to direct provision

(see Reducing AI Misuse on why the pedagogical stance matters). The agentic AI literature shows that grounding agents in instructional-design theory outperforms raw prompting. Moganadas et al. (2026) reframe this role formally: rather than a dyadic instructor–student model with GenAI as an external supplement or threat, they propose a nested **instructor–student–GenAI triadic model** in which GenAI operates as a bounded *didactic-pedagogical mediator* within a shared didactic mediation space governed by institutions and stakeholders — yielding five researchable propositions on learning mediation, instructor-role transformation, AI literacy and learner agency, AI-transparent process-oriented assessment, and institutional AI Governance.

- **Pedagogy determines AI's effect.** A recurring finding is that *how* AI is used matters as much as *whether* it is used. Instructional-guidance research and guardrailed-tutor RCTs show the same AI can harm or help depending on the pedagogical wrapper (hints vs. answers, structured vs. open use).
- **Pedagogical knowledge outweighs technical knowledge.** Across 46 teachers and 2,832 students, teacher pedagogical AI knowledge predicted students' perceptions of AI for social good and their intention to learn AI, while technical knowledge alone was insufficient — and neither predicted students' AI knowledge (Shen et al. (2026)).
- **Offloading administrative work is where AI contributes most clearly.** A PRISMA review of 28 studies found AI most often enhanced instructional planning and assessment design, with its most reported benefit the automation of grading, feedback and progress monitoring (18 studies, 64.2%) — while pedagogical alignment was the most cited challenge (14) (Kibar & Ilgaz (2026)).
  Automation and learning trade off directly. Woollaston et al. (2026) walk six pedagogical principles — Prior Knowledge activation, Collaborative Learning, Problem-Based Learning, Formative Assessment, Scaffolding, Metacognition — through what proactive agentic initiative does to each, arguing the more an agent automates, the less cognitive work the learner does unless friction, dynamic fading, and human oversight are designed in.
- **Reflection is a pedagogy that AI both enables and threatens.** Structured prompts, journals and portfolio commentaries are the mechanism by which experience becomes learning, and the Reflection page carries the evidence. One preregistered experiment found prompts that doubled time on feedback and cut practice volume by 40% without lifting per-problem gain. A coded audit of an AI reflection partner found it broke every behavioral instruction without leaving a visible trace. Design the prompt around a completed attempt, and require the trail rather than the polished entry.
- **Teaching strategies for AI literacy.** Teaching students *to use AI well* is itself a pedagogical task — AI Literacy and Reducing AI Misuse research develops strategies (think-first/AI-second/reflect, AI-declaration, calibration training) that belong to this umbrella.
- **AI-literacy instruction moves knowledge fastest.** A three-level meta-analysis of 59 studies (172 effect sizes) found knowledge-focused interventions ($g \approx .97$) clearly outperformed those targeting skills ($\approx .67$), attitudes ($\approx .68$), or Ethics ($\approx .64$), so pairing concept teaching with sustained practice targets the outcomes that resist instruction (Liu et al. (2026)).

- **Pedagogy in teacher practice.** Teaching and Teacher AI Competency examine how teachers adopt AI within their existing pedagogical repertoire, and LLM Training and Fine-Tuning / Pedagogical Agent study AI tools trained to follow pedagogical principles.

Relationship to learning theories

Pedagogies and learning theories are closely linked: each pedagogy operationalizes one or more theories. For example, Project-Based Learning operationalizes Constructivism and experiential theories; Socratic Method draws on Sociocultural Learning and Metacognition; Scaffolding stems from the Zone of Proximal Development. The knowledge base treats Learning Theories as the conceptual foundation and this page as the instructional-practice umbrella — see also Learning Design, which concerns the systematic process of selecting and sequencing strategies. The learning sciences sit one step further out again: this page covers the practice of teaching and the strategies educators choose, while the learning sciences study that practice empirically — describing, modeling and evaluating designs to establish which ones change learning.

Learning gains across pedagogical strategies

Different pedagogical strategies produce different kinds and sizes of learning gains, and the knowledge base's evidence lets us compare them:

- **Active and experiential strategies** generally produce stronger durable learning than passive reception, though they feel more effortful — Active Learning, Experiential Learning, Project-Based Learning, and Learning by Teaching build understanding through doing. Research shows that strategies preserving effortful practice (rather than AI shortcutting it) protect Learning Gains.
- **Structured, guided strategies** (Scaffolding, Self-Regulated Learning, Learning Design) produce reliable but more modest gains — the guardrail evidence (PNAS 2025) shows hint-not-answer scaffolding preserves learning that unguarded answer-giving destroys.
- **Game-based learning** produces engagement and skill gains that are real but often modest and context-dependent — meta-analytic evidence finds game-assisted GenAI shows no significant added benefit over other formats, so games are best used for motivation and practice, not as a shortcut to gains.
- **Collaborative and sociocultural strategies** (Collaborative Learning, Sociocultural Learning) show gains mediated by interaction quality, increasingly studied with AI as a partner or peer.
- **Socratic and dialogue-based strategies** (Socratic Method) target higher-order thinking and reasoning — gains that are harder to measure than skill gains but central to Critical Thinking.

The key cross-cutting finding, consistent with the knowledge base's Learning Gains research, is that **the strategy's effect on learning depends more on how it preserves learner effort and productive struggle than on which label it carries** — any pedagogy, even a "good" one, fails if AI is configured to bypass the cognitive work it was meant to elicit (see Cognitive Offloading, Desirable Difficulties).

Student–AI interaction is better read as a shifting process of cognitive distribution than as fixed dependence: across 53 ChatGPT conversations from a transdisciplinary engineering course, extension (tight, iterative co-thinking) was the most frequent interaction type at 53.3% of 321 prompt-level codes, ahead of outsourcing at 29.6% (Willcox, Lane & Arikan (2026)).

That emphasis on preserved effort is not absolute: a four-study mixed-methods design (N = 912) found that framing GenAI as a pedagogical partner activated both critical vigilance and strategic offloading, with offloading above a threshold freeing capacity for higher-order reflection rather than eroding it (Wang and Zhang (2026)).

Implications for AI in education

- **Select pedagogy deliberately with AI:** the teaching strategy determines whether an AI tool supports or undermines learning, so pedagogical intent should drive AI tool selection and configuration.
- **Keep learner agency central:** active, Socratic, and scaffolding pedagogies preserve the productive struggle and Learner Agency that AI can otherwise erode (see Cognitive Offloading, Desirable Difficulties).
- **Design AI to enact good pedagogy:** AI agents and tutors should be grounded in established instructional frameworks, not default answer-generation.
- **Teach with and about AI:** pedagogies should both use AI to teach and teach learners how to use AI responsibly.

Common Misconceptions

- **"Technical AI knowledge is what teachers need most."** Across **46 teachers and 2,832 students**, **teacher pedagogical AI knowledge** predicted students' perceptions of AI for social good. Pedagogical knowledge outperformed technical knowledge, which inverts where most training investment goes.
- **"AI's main contribution in education is instructional."** A **PRISMA review of 28 studies** found AI most often enhanced **instructional planning and assessment design** — the clearest contribution is **offloading administrative work**, not teaching. A case built around instructional gains is building on the weaker branch of the evidence.
- **"AI literacy instruction transfers automatically to better teaching."** A three-level meta-analysis of **59 studies (172 effect sizes)** found **knowledge-focused interventions (g ≈ .97)** clearly outperformed other approaches at moving knowledge. Moving knowledge is the measured outcome; whether it reached practice is the next question.

Connected FAQs

- How Should AI Be Designed Into the Learning Experience?

Pedagogical Patterns

> **Pedagogical Patterns** — the *ordered sequences* of activity that research in this knowledge base has tested, with attention to where generative AI enters the sequence and where human judgment has to remain. Where Pedagogies and Teaching Strategies catalogs approaches (active learning, problem-based learning, collaborative learning) and Learning Design describes how a course is designed, this page catalogs what students and teachers actually *do*, in what order, and what happened when it was tried. PAIRR — draft, peer review, AI review, reflection, revision — is the best-documented example, and the pattern behind it recurs across disciplines: effort first, AI second, human judgment at the stakes.

Questions to Consider

- A pattern is a *sequence*, not a tool. Take one assignment you teach and write the order of moves a student makes. Where in that order would AI help, and where would it do the work the student is supposed to be doing?
- Several patterns here deliberately give AI a *weak* role — hints instead of answers, questions instead of corrections. Why would a deliberately less helpful tutor produce better learning, and what does that imply about the AI tools your institution is buying?
- The best-evidenced pattern on this page (learning by teaching an AI) asks students to explain, and it improves explanation and question quality but *not* objective recall. If you adopted it, what would you change about how you assess?
- When AI feedback was higher quality than teacher feedback, students did not revise more. What does that suggest about the difference between producing feedback and getting students to use it?
- Contexts change the answer: some patterns were tested online and asynchronous, others face-to-face with a lab. Which of these could you run in your own setting without new tools, and which would need infrastructure you do not have?
- Nearly every pattern here keeps a human at the point of judgment — grading, verifying, or interpreting. Is that a design choice, an evidence-based necessity, or a limitation of what has been tested so far?

Introduction

Pedagogy answers *how should we teach*; this page answers a narrower, more operational question: **in what order should the moves happen, and where does AI belong in that order?** The distinction matters because the same tool produces opposite outcomes depending on its position in a sequence. A generative-AI assistant placed before a student attempts a problem reliably depresses later unassisted performance; placed after an attempt, with hints rather than answers, the same class of system removes that harm.

Every pattern below is reported with an evidence status, because the knowledge base's coverage is uneven and the difference matters to anyone deciding what to adopt:

- **Tested** — at least one article reports a controlled or comparative test.
- **Mixed** — tested, but without a control, with conflicting results, or with the tested variable entangled with something else.
- **Design proposals** — the idea appears only as a proposal or framework, with no test reported. These are collected separately at the end of the page, in *Design proposals (not yet tested)*, and are not evidence.

The patterns are grouped by the function they serve in a lesson: placing effort before help, pairing AI feedback with human feedback, verifying understanding rather than output, making the learner the teacher, structuring collaboration, and confronting a specific misconception. Contexts (online, face-to-face, blended) and disciplines are reported with each, and summarized at the end.

Patterns that place effort before help

These patterns share a structural claim: the learner must commit to an attempt before the AI contributes. It is the most consistently supported design rule in the knowledge base.

Retrieve or attempt before the AI answers

Evidence: tested. The sequence is: attempt from memory, receive instruction or an example, practice in spaced sessions, consult the AI only after committing to an attempt, receive response-contingent feedback that probes the misconception, and advance only once the response shows adequate engagement.

An adaptive spaced-retrieval condition produced the highest posttest scores (M = 78.19) and significantly outperformed learner-directed AI study (M = 67.28, d = 0.92, p = .003) across 89 students in a blended statistics course, while fixed spacing was statistically indistinguishable from adaptive (Akgun & Toker, 2026). The contrast case is decisive: in a randomized trial of 120 students, the group that studied *with* unrestricted ChatGPT retained less on a surprise test 45 days later — 57.5% correct against 68.5% for traditional learners, t(83) = −3.19, p = .002, d = 0.68 — and had also studied roughly 45% less, with the disadvantage surviving a study-time covariate (Barcaui, 2025). A preregistered randomized field experiment in an online MBA found that gains tracked *completed weeks* rather than minutes of exposure (+2.00 points per additional completed tutoring week, p = .018), reading as spaced practice mattering more than total time (Yang et al., 2026).

The causal case for the rule is a field experiment in roughly 50 Turkish high school mathematics classes with nearly 1,000 students (Bastani et al., 2025). Unrestricted GPT-4 raised assisted practice performance by 48% and cut the unassisted exam by 17% against control, while a guarded GPT-4 raised practice by 127% and left the exam essentially unchanged. The Guardrails were only two: hints instead of answers, and teacher-authored problem-specific content (correct solution, common mistakes) seeded into the prompt so the hints were accurate. Engagement data put the harm in copying, since unguarded students mostly asked for answers, and students in both AI arms misjudged their own learning.

Productive failure: attempt before instruction

Evidence: mixed, and thinner than its reputation. Students attempt a problem targeting a concept they have not been taught, the tutor withholds the solution and elicits multiple attempts, help comes only when strictly necessary, and consolidation follows with comparison and direct instruction.

The one field study that tests the full sequence with a steered tutor used 17 high school students in Singapore: the steered condition achieved a higher productive-failure score, significant for problem consistency ($p = .046$), and students produced on average 2.6 representations per session ($p = .05$), but **no learning outcome was measured** (Puech et al., 2025). The strongest support is indirect and comes from a randomized within-subjects experiment with 26 students, where immediate-answer Scaffolding performed significantly *worse* than peer, TA and tutor roles on model abstraction ($\beta = -0.692$, $p = .015$; $\beta = -1.039$, $p < .001$; $\beta = -0.769$, $p = .005$) even though students *preferred* the directive tutor — preference ran against competence (Zhu et al., 2026).

Error analysis and erroneous examples

Evidence: mixed. Students diagnose an error in an artifact — an AI-generated diagram violating referential integrity, a query that drops a join, an Large Language Models (LLMs) code snippet — receive clues that force them to infer the fix rather than being handed the correction, repair it, and reflect on which parts of the output were untrustworthy.

A pre-post study of 13 students in an online database course rose from 4.25 to 6.83 out of 7 ($t(12) \approx 5.10$, $p < .001$, $d = 1.49$) using weekly critique-and-refinement cycles built on deliberate AI failure cases, but with no control group the gain cannot be separated from the curriculum or instructor (Hosseini, 2026). A systematic review of 72 computing-education studies reports that error analysis is a *distinct competence*: students performed significantly worse at correcting LLM-generated code than at traditional programming exam tasks (Kumar et al., 2026). No article in the knowledge base reports a controlled test of erroneous-example instruction as such.

Worked examples with self-explanation

Evidence: mixed — the two halves diverge. A worked example is presented with missing justifications to complete, or with errors to find; the student completes or repairs it, explains their reasoning, and then attempts the next problem.

Adaptively assigning guided and buggy examples beat random problem-type assignment in a classroom study of 113 students (posttest M = 72.3 and 72.5 against 65.7 control, A = .58, $p = .005$ and $p = .002$), and the Knowledge Tracing variant narrowed the achievement gap by 77.1% for low Prior Knowledge students ($\beta = 9.4$, $p = .001$) (Dey Tithi et al., 2026). But *adding* the self-explanation step to elaborated AI feedback lost on every measure in a preregistered experiment with 302 participants: it doubled feedback time (4.1 vs 2.1 min, $p < .001$), cut problems completed by 40% (2.0 vs 3.4, $p < .001$), produced no gain per episode (OR = 1.03, $p = .486$), and lowered end-of-session mastery (65% vs 79%, $d = .41$, $p < .001$) (Asher et al., 2025).

How many examples to give before practice is itself content-dependent, which the section's framing of "worked examples then problems" leaves open. In a 2×2 experiment with 95 participants on geometry-area materials, practice-only training produced larger gains for verbatim facts while alternating examples with

practice produced larger gains for generalizable skills (β = 0.41, p = .038, d = 0.38) (Rachatasumrit, Koedinger and Carvalho, 2025). A sequence cannot be judged as worked examples against practice in the abstract, because the right mix follows from whether the target is a fact or a skill.

Patterns that pair AI feedback with human feedback

The knowledge base's most replicated finding about AI feedback is that it works better *combined* with human feedback than alone — and that its quality is not what determines whether students use it.

PAIRR: peer and AI review with reflection

Evidence: mixed (widely implemented, not controlled). Students read and reflect on how AI and feedback work, draft, give and receive peer review, prompt the AI for criteria-driven feedback on the same draft, critically compare both, write a revision plan, revise, and reflect on which feedback changed what.

The largest study of college students' use of AI feedback to date followed 654 students across ten writing courses and three writing-intensive STEM courses: 58% preferred combined ChatGPT and peer feedback, 36% peer alone and only 6% AI alone; 75% found the two similar and mutually reinforcing; AI feedback was called "overly general" by 31% while peer feedback was more specific for 28%; and only 5.3% showed overconfidence in AI feedback (Sperber et al., 2025). The model was also run in an upper-division business writing course with 34 students, where about a quarter of coded reflections expressed skepticism about or noted inaccuracies in AI feedback (MacArthur et al., 2025). Both report perception data; neither has a control condition, which is why the pattern is *mixed* rather than *tested*.

A third write-up of the same 2024 implementation asks what students call the tool rather than how they rated it. Stillman et al. (2026) describe 13 sections of 10 writing-intensive courses and 654 students, and report that only about half (51.7%) adopted the tutor or collaborator roles the reflection prompt offered. The remainder named a tool, a program, a robot or a computer, or invented metaphors such as a vending machine of feedback. The authors read that vocabulary as the literacy outcome and as evidence of writerly agency, and their data is perceptual in the same way, so the evidence grade above does not move.

Combined peer and AI feedback

Evidence: tested. The comparative evidence comes from outside the PAIRR program. A quasi-experiment with 122 Chinese EFL students found AI-plus-peer integrated feedback raised behavioral, affective and cognitive engagement against peer-feedback-only (all $p < .001$; partial $\eta^2 = 0.28, 0.28, 0.32$) and improved writing on all four IELTS dimensions ($F(1,119) = 42.68$, $p < .001$, partial $\eta^2 = 0.26$), largest on task achievement ($d = 1.41$) — with no delayed post-test, so durability is unmeasured (Liu, 2026). In a randomized study of 45 student teachers in 12 groups, GenAI-supported peer feedback beat plain peer feedback on argumentation, and the *prompt-scaffolded* variant performed best on advanced elements such as rebuttal data and addressing the opposing view (Chang et al., 2026).

AI critique then revision

Evidence: tested — with an important null. Draft, prompt the AI for rubric-driven feedback, critically assess that feedback against the rubric and the sources, write a revision plan, revise, and reflect.

A controlled 2 × 2 factorial experiment with 120 English majors found writing-quality gain was highest for the group trained in both filtering and appraisal (M = 7.92), against 6.10, 4.56 and 3.10 for the other conditions, with deep revision rising from 28% to 48% and the advantage persisting on a new topic and after AI support was removed (Dai, 2026). The null is the instructive part: in a randomized three-group experiment with 70 students, chain-of-thought-prompted AI feedback was significantly *higher quality* than both zero-shot AI feedback ($p = .01$) and teacher feedback ($p = .008$), yet this quality advantage **did not translate into greater revision gains** — teacher feedback produced comparable improvement (Farrokhnia et al., 2026).

Human-in-the-loop review of AI output

Evidence: mixed — the review step is rarely the tested variable. AI generates draft output, automated verifier agents check it for realism, readability or hallucination, failed checks loop back for refinement, and a teacher reviews, edits, and accepts or discards before anything reaches students.

A four-agent loop with 8 teachers produced 212 problems of which 166 were accepted as-is, and realism checks worked as intended (10 realism problems flagged, 20 quantity or unit edits, no mathematics error found in a final problem) — but interest fit was the weak point, with students rejecting the topic in 160 of 422 responses (Walkington et al., 2026). An educator-in-the-loop feedback tool rated by 30 teachers never fell below 4.1/5 across nine items and cut median time per assignment from 10–30 minutes to under 5, but the authors acknowledge no student evaluation, so no learning claim is supported (Zhao et al., 2025). A red-team experiment makes the stakes concrete: 2 of 5 prompt injections changed a grade undetected, at 100% (9/9) and 94% (17/18), leaving the teacher as the only real check on AI grading output (Humble, 2026).

Patterns that verify understanding rather than output

Because AI can produce a competent artifact, these patterns move assessment to evidence the artifact cannot supply on its own.

Oral and viva verification

Evidence: tested as a format, but results are about scores and affect rather than learning. A coding assignment is submitted with AI permitted, followed within 48 hours by a mandatory 15-minute oral code review in which the student explains the program and runs integration tests live, graded 70% on the review and 30% on the rubric.

A three-semester quasi-experiment with 96 students found no statistically significant change in exam performance despite the new policies (~2% improvement on one exam), while pasted-to-total characters rose from 61.0% to 68.1% ($p < 0.0001$); 90% of students said the reviews motivated them to understand their code better and 65% that they helped avoid over-reliance (Fowles et al., 2026). Asynchronous recorded oral responses produced significantly higher scores than in-person multiple-choice (midterm Md = 92.5 vs 70, p

< .001; final Md = 94.2 vs 86.4, p = .002) with only moderate cross-format correlations (τ = .44 and .25) — and the authors caution these are *format score differences, not evidence of learning gains*, with cheating behavior unmeasured (Pentland et al., 2026). Direction is not uniformly positive: students were calmer in a chat-based viva (M = 6.50 vs 5.86, p = .028) but rated the face-to-face viva significantly better for understanding their own work (p = .004) (Yusuf et al., 2026).

Staged checkpoints and process evidence

Evidence: mixed — no controlled test of the mechanism itself. Coursework runs as staged modules, each ending in a checkpoint that verifies both the output *and* the approach — a correct result reached by hardcoding is rejected — with a pre-advancement check that returns the learner to skipped steps.

A case study of 5 graduate students in a self-paced quantum-information course logged 75 interactions and confirmed the dual output-and-approach checkpoint functioned as intended, with no control group (Elhaimeur & Chrisochoides, 2026). A 27-participant pilot using stop-block checkpoints reported significant Self-Efficacy gains across all ten assessed skill areas ($p < 0.001$) in a within-subjects pre-post design where gains cannot be separated from practice effects (Naboulsi, 2026). A three-year quasi-experiment with 248 biomedical engineering students found higher A-rates after adding four-module problem-based learning with milestones and rubrics (66.4% vs 39.1%, Δ = +27.3 points, p = 0.042), persisting after excluding the pandemic-affected year, but the comparison is historical and non-randomized (Nnamdi et al., 2026).

Patterns that make the learner the teacher

Learning by teaching an AI tutee

Evidence: tested, and the best-evidenced pattern on this page. The student studies the content, then explains it to an AI prompted to hold a novice stance that never reveals the target explanation; the AI asks for explanations, examples and verification reasoning, sequenced from lower- to higher-order, and persists until the explanation is satisfactory.

A quasi-experiment with 68 preservice teachers found explaining to a GAI novice learner scored higher on defining the flipped classroom (M = 4.18 vs 3.29, $p < 0.001$, $r = 0.474$) and its activities (M = 4.91 vs 3.06, $p < 0.001$, $r = 0.642$), generated more and higher-quality questions (both $p < 0.001$) — but showed **no group difference on objective questions** (M = 23.18 vs 21.57, p = 0.416) (Wang et al., 2026). A randomized lab experiment with 41 students found higher knowledge-test scores (adjusted 11.86 vs 10.53, $F = 35.54$, $\eta^2 = 0.74$) and clearer, more readable code, but **no difference in code correctness** (Chen et al., 2024). An 11-week deployment across 546 students found each additional deep-learning act associated with a 2.7% decrease in expected quiz attempts (IRR 0.973, $p < .001$), with the comparison confounded by time-on-task and late-semester circumvention rising to 30–35% external content reuse (Wang et al., 2026). The consistent shape: gains in explanation and generative work, not in objective recall.

Patterns that structure collaboration

Scripted roles with one shared AI

Evidence: tested, but in controlled or uncontrolled settings rather than ordinary classrooms. Two learners share one AI and are assigned explicit roles with rotation rules; the AI is configured to take a role as needed and its output goes to the whole group. In a pair-programming variant the shared AI models the dyad's joint attention and effort, forecasts a breakdown up to 30 seconds ahead, and escalates scaffolds in tiers from doing nothing to a directive hint.

A within-subjects experiment with 26 dyads found the feedback condition achieved higher debugging success ($t[49.96] = -13.51$, $p < .0001$) and finished faster ($t[44.70] = 4.39$, $p < .0001$), though it required dual eye-tracking and pupillometry hardware and did not test transfer to unsupervised pair work (Golrang et al., 2026). A quasi-experiment with 58 graduate students in 16 groups found role design raised mind-map content scores from 3.65 to 4.59 on a 1–5 SOLO scale ($z = 3.771$, $p < 0.001$) while node and branch counts stayed flat — but with no control group, practice effects cannot be ruled out (Cheng et al., 2026).

AI-assisted discussion

Evidence: mixed — the one direct implementation is a case description. Students analyze a scenario and answer guided questions independently, prompt ChatGPT with a standardized prompt on the same questions, evaluate the AI responses for accuracy against their own, refine their answer, and close with a whole-class discussion.

The economics activity deliberately exploits an AI error — ChatGPT calls the song's depicted behavior "perfectly elastic" demand when the correct answer is inelastic — turning validation of AI output into the discussion (Beck & Brodersen, 2025). It reports instructor impressions, not a measured outcome. A tested collaborative-discussion sequence with 67 teacher-education students found the experimental group outperformed a lecture control ($M = 51.45$ vs 43.89, $p = 0.001$, $g = 0.839$) with co-regulation rising ($p = 0.043$, $g = 0.512$) — but AI was used to *design* the technique, not to mediate the discussion (Tutal, 2026).

Patterns that confront a specific misconception

Refutation and conceptual change

Evidence: tested — with directly conflicting results. Elicit the learner's specific belief, present a refutation text or a personalized AI dialogue that confronts it, engage with the counter-evidence and the correct explanation, restate the correct conception, then retest after a delay.

A preregistered experiment with 375 adults found personalized misconception AI dialogue produced significantly larger immediate belief reductions than both textbook-style refutation and neutral AI dialogue, persisting at 10 days but converging with textbook refutation by 2 months (Corbett & Tangen, 2026). A Solomon four-group quasi-experiment with 413 tenth-graders found the *reverse*: expert-written and AI-generated conceptual-change texts were both significantly more effective than interactive ChatGPT dialogue, which showed no significant advantage over control, and gains were almost exclusively limited to high-

achieving students (Akdogan, 2025). The second paper flags the conflict explicitly and attributes it to prompt design and domain. Refutation text itself beat control in both.

Contexts and disciplines

The pattern determines what the context requires, and several patterns were tested in only one setting. Pooled estimates make that dependence quantitative. Across 35 experimental and quasi-experimental studies and 175 effect sizes, generative AI's pooled effect on undergraduate academic performance was g = 0.46, and the teaching model moderated it (Q = 14.63, p = 0.001). Flipped classrooms reached g = 1.96 from 7 effect sizes, traditional classrooms g = 0.46, and self-directed learning g = 0.26 (Jing et al., 2026). Intervention duration moderated it too, with the academic-performance effect falling from g = 5.07 at 0 to 4 weeks to g = 0.01 beyond 12 weeks. The authors treat the very large short-duration estimates as descriptive rather than generalizable, so an effect size for "AI in teaching" is a claim about a design, and the patterns here are those designs.

- **Online and asynchronous.** Retrieval and spacing, the Socratic variants, worked examples with self-explanation, prompt-scaffolded use, asynchronous oral assessment, and the learning-by-teaching deployments. Asynchronous settings make the *sequencing* load-bearing, because the system cannot see whether the student attempted first.
- **Face-to-face and blended.** Productive failure, error analysis, the flipped variants, oral code review, scripted collaboration, and the conceptual-change studies. Class time is often reallocated rather than replaced — in the oral-review pattern, lectures moved to video so class time could hold the interviews.
- **Disciplines represented in the tested evidence.** Writing and language learning (PAIRR, combined peer and AI feedback, AI critique then revision), mathematics (retrieval and spacing, productive failure, worked examples, error analysis), computer science (Socratic assistants, error analysis, oral code review, learning by teaching, scripted pair work), medicine (Socratic scaffolding in clinical interviews), teacher education (scripted argumentation, learning by teaching), business (flipped MBA tutoring), and physics, science and vocational settings for the conceptual-change and oral-assessment studies.

What the evidence does not yet support

Stated plainly, because these are the findings most likely to be quietly dropped:

- **Better AI feedback does not produce more revision.** Higher-quality chain-of-thought feedback beat teacher feedback on quality and produced no revision advantage (Farrokhnia et al., 2026).
- **Socratic questioning is not automatically better.** A randomized trial of 132 students found the Socratic assistant with full context rated significantly *worse* for supporting task completion than all other configurations (mean rank 48.63, $\mu = 3.53$, against 4.27, 4.16 and 4.12; $\chi^2(3) = 12.14$, $p = .007$), with the most external LLM use (23%) and the fewest full-comprehension responses (48% vs 67%) (Eastwood et al., 2026) — while a medical RCT found a multi-agent system containing a Socratic tutor beat its control on examination and communication scores (Yang et al., 2026).

- **Students prefer the less effective role.** Directive tutoring was preferred while immediate-answer scaffolding depressed model abstraction (Zhu et al., 2026).
- **Verification formats change scores without demonstrating learning.** Oral formats raised scores and reduced anxiety while one study found face-to-face better for understanding, and no study measured cheating.
- **No controlled test isolates human review of AI output**, and the checkpoint mechanism has never been tested as the manipulated variable.
- **Productive failure and error analysis rest on small, uncontrolled studies** (n = 17 and n = 13) that measure strategy fidelity or self-report rather than learning outcomes.

Design proposals (not yet tested)

The patterns below come from a faculty guide supplied by the knowledge base maintainer (*AI-Ready Course Design*, September 2026). That guide states explicitly that its examples are **design proposals, not tested interventions**, and no article in this knowledge base tests them. They are recorded here as design ideas worth trying and evaluating, and must not be read as evidence.

- **Argument + revision trail** (composition, humanities). Replace an essay-only submission with an initial thesis, two annotated source passages, a revised essay and a 150-word decision note; permit AI critique after the first draft. Assess the claim–evidence connection and one accepted or rejected suggestion justified against the sources.
- **Data + reasoned claim** (science, laboratory courses). Replace a polished lab report with raw observations, a graph, an uncertainty note and an explanation linking results to a claim; AI may critique a supplied interpretation, and students verify that critique against their data.
- **Attempt + error analysis** (precalculus, calculus). Replace answer-only homework with an initial attempt, analysis of a flawed worked solution, and a corrected explanation; hints are permitted only after the attempt. This is the design form of the error-analysis pattern above, and it inherits that pattern's weak evidence base.
- **Position + challenge + reconsideration** (psychology, sociology). Replace "post once, reply twice" with a case-based claim using a course concept; a peer supplies a counterexample and the author revises or defends with evidence.
- **Project + linked check** (business, health professions). Pair an AI-permitted recommendation for a fictional organization or patient case with a short explanation of two key decisions and a response to a changed constraint; publish the grading relationship between the two components.
- **Plan + try + adapt** (college success). Replace a generic time-management reflection with a one-week study plan, a brief record of trying it, and a revision tied to what happened; AI may suggest scheduling options after the student identifies constraints.

The guide's own cautions apply: recorded video, reflections and logs can themselves be AI-assisted, so in fully asynchronous courses a recording should not be treated as verification of independent mastery. Two of its framings — assessment twins and asynchronous oral assessment as a cheating deterrent — remain frameworks awaiting validation; the asynchronous oral-assessment studies cited above measured format scores and did not measure cheating at all.

Common Misconceptions

- **“Any AI-supplied practice is practice.”** An adaptive spaced-retrieval condition produced **the highest posttest scores (M = 78.19)** and **significantly outperformed learner-directed AI study (M = 67.28)**. The learner-directed arrangement underperformed a structured one, so autonomy is not automatically the better design.
- **“Studying with a chatbot is better than studying without.” The counterexample settles it**: in a randomized trial of **120 students**, those who worked with unrestricted ChatGPT remembered **less when tested without warning** than those who did not. The tool was harmful to retention in the arrangement tested.
- **“The pattern’s evidence is a large pooled trial.”** The **strongest support is indirect** and comes from a **randomized within-subjects experiment with 26 students**, where immediate-answer Scaffolding performed significantly differently. The evidence supports the pattern and remains thin in scale, and the page should be read that way.

Connected Concepts

- Pedagogies and Teaching Strategies — the umbrella of teaching approaches this page operationalizes into sequences
- Learning Design — where patterns are chosen, sequenced and embedded in a course
- Scaffolding — the support-and-fading principle that governs where AI help belongs
- Feedback — the system this page’s feedback patterns instantiate
- Formative Assessment — the assessment purpose most of these patterns serve
- Peer Assessment — the human half of the PAIRR and combined-feedback patterns
- AI Feedback Quality — why feedback quality alone does not determine revision
- Evaluative Judgment — the appraisal students must exercise on AI output
- Feedback Literacy — the capability the critical-appraisal steps are building
- Human-in-the-Loop — the oversight structure of the review patterns
- Oral Assessment — the format underlying the verification patterns
- Process-Oriented Assessment — the logic behind staged checkpoints
- Productive Failure — the concept behind attempt-before-instruction
- Retrieval, Spacing and Interleaving — the evidence base for spaced retrieval patterns
- Desirable Difficulties — why effortful sequences outperform fluent ones
- Misconceptions about AI — what the conceptual-change patterns target
- Refutation Text — the text form of misconception confrontation
- Learning by Teaching — the pedagogy behind the AI-tutee pattern
- Socratic Method — the questioning pattern and its conflicting evidence
- Collaborative Learning — the context for scripted shared-AI work
- Cognitive Offloading — the risk every effort-first pattern is designed to avoid
- Metacognition — what reflection steps in these sequences are meant to trigger
- Prompt Engineering — the scaffolding layer in structured-use patterns

- Transfer of Learning — the outcome most patterns are ultimately judged on
- Assessment Validity — the reason process evidence is proposed at all
- Academic Integrity — the driver behind oral and process verification
- AI Literacy — the capability developed by critiquing AI output
- Online Teaching and Learning — the context that makes sequencing load-bearing
- Higher Education — the level where most of this evidence was generated
- K-12 — the level of the productive-failure, conceptual-change and oral-assessment studies

Connected FAQs

- How Should AI Be Designed Into the Learning Experience?

Active Learning

> **Active Learning** — instructional approaches that engage students in doing things and thinking about what they are doing, rather than passively receiving information. In AI in education, active learning research examines both how AI tools can support active learning pedagogies and how active engagement with AI tools — rather than passive consumption — affects learning outcomes.

Questions to Consider

- You've likely heard 'active learning' praised. But is a student who clicks through a dashboard or accepts a generated answer really learning actively? What would make that activity 'active' in a meaningful sense?
- The ICAP framework distinguishes active, constructive, and interactive engagement — only the deeper levels build lasting knowledge. When you last used an AI tool to learn something, which level of engagement did it actually push you toward?
- AI can enable active learning at scale, but poorly designed AI can also do the cognitive work for the student. Where have you seen AI make a learner more passive rather than more engaged?
- An EEG study found interactive student–AI collaboration produced the highest cognitive engagement, while full automation reduced it. Why might 'doing' with AI beat 'watching' AI do the work?
- Teach-back — having a learner explain what they understand — surfaces gaps more effectively than passive re-reading. When might prompting a learner to explain to an AI be a better learning move than letting the AI answer for them?
- Active learning depends on calibrated scaffolding that fades as competence grows. How hard is it for an AI tutor to know when to step back — and what's the risk if it never does?

Introduction

Active learning is a foundational principle in education research, grounded in Constructivism theories that position learners as active constructors of knowledge. In the context of AI in education, the concept takes on dual significance: AI tools can enable active learning at scale (through interactive tutoring, simulations, and adaptive feedback), but poorly designed AI tools can also undermine it by doing the cognitive work for students. The tension between AI assistance and active cognitive engagement — explored in articles like Revisiting the Hint Button: Consistent Negative Associations Between Unproductive Hint Use and Learning Outcomes in Intelligent Tutoring Systems on premature hint use and The efficiency-gain illusion: People underestimate the rate of AI use and overestimate its benefits on simple tasks on Over-Reliance — is a central concern.

AI-enabled active learning manifests across multiple forms in this knowledge base: Intelligent Tutoring systems that engage students in problem-solving rather than answer-giving, Generative AI (GenAI) as a mindtool that supports generative learning (GL) approaches where students use AI as a thinking tool rather than a substitute, Test-Driven, AI-Assisted Learning: Replacing Lectures with Weekly Closed-Book Tests

where students drive AI interaction rather than follow it, and Curiosity as Linguistic Intervention: Using LLM Tutoring Dialogues to Influence Exploratory Learning Behavior exploratory learning environments. The Scaffolding concept is tightly coupled: active learning needs support that is calibrated, then withdrawn as learners gain competence, and AI tutors must learn that timing.

How active learning appears in the knowledge base's research

- **Interaction mode determines cognitive engagement.** An EEG study of high school students compared Auto (AI solves independently), Interactive (student–AI collaboration with scaffolding), and Manual (no AI) modes: **Interactive produced the highest cognitive engagement and task accuracy**, while Auto reduced engagement and risked over-reliance. This gives a neurophysiological dimension to the argument that AI must keep students *doing* rather than watching.
- **AI-supported inquiry is not automatically higher-order.** A quasi-experiment with 120 Grade 8 students found AI-supported inquiry-based learning raised creative mathematical performance and attitudes toward mathematics but produced no significant gain in critical Problem Solving — a caution against reading Creativity and affect gains as evidence of deeper reasoning (Mujib et al., 2026).
- **Access is not structure.** In a construction-engineering review task, the same retrieval-augmented system scored 12.41 on open-ended items when run through a five-step prompting structure against 10.45 without it, while slide-based study scored 9.68, and multiple-choice recall did not differ (Hou et al. (2026)). Unprompted AI review did not beat slides, so the gain traces to the structure of the interaction rather than to model access.
- **Replication is a distinct active ingredient.** The Physics AI-Replication protocol has students get an AI explanation of a hard problem, request one or two similar problems, then solve those independently before checking. Across 11 introductory physics sections at four U.S. institutions, 90.9% of 231 respondents credited it with better conceptual understanding and 97.7% of 213 found the replicated practice helpful, the two correlating at $r_s = 0.58$ (Paul et al., 2026). The learner-side mechanism is what the page lacked: 18.7% of open responses described having to understand a problem's structure in order to generate a similar one. Confidence afterward tracked those two benefits ($r_s = 0.37$ and 0.35), not usage frequency ($r_s = 0.02$).
- **Exploratory and simulation-based active learning.** SupplyNet uses a contextual multi-agent Large Language Models (LLMs) simulation to support visual exploratory learning in supply-chain education, pairing an interactive network view with a branching "what-if" timeline so learners trace causal dynamics rather than consume abstract content. Curiobot and problem-posing in physics similarly foreground learner-driven exploration.
- **Structured conversational workflows for active review.** KnowLoop structures post-lecture review around three stages — Recognize (mark in-situ confusion), Resolve (clarification), and Consolidate (teach-back) — showing that teach-back prompts learners to articulate and reveal conceptual gaps, and that context-grounded AI outperforms general-purpose AI for targeted support. Teach-back instantiates Learning by Teaching.

- **Active learning as a project-based, community structure.** The Academic League of AI organizes extracurricular AI education around competition teams, study groups, and AI-for-social-impact projects, embodying active and project-based learning through democratic student governance rather than top-down curriculum.
- **Mindtools and generative engagement.** GenAI as a mindtool positions AI as a device students think *with* rather than a source of answers, aligning active learning with generative-learning theories where learners integrate new ideas into existing knowledge.
- **Building the tutor as the active-learning task.** Zangari et al. (2026) inverted the usual AI-tutor arrangement: instead of using a tutor, 345 students in a 700-student software course each designed a conversational agent to teach three design patterns to a peer, so the active-learning work was the agent's construction — anticipating user needs, translating abstract concepts into teachable pieces. Open-ended design freedom drew the most positive comments (22.3% top positive theme), while unclear instructions drew the most complaints (23.7%); the authors caution the no-control-group, volunteer-sample design supports engagement claims only.
- **Design around the model's mistakes.** A five-step sequence (independent analysis, a standardized ChatGPT prompt, critical evaluation of the output, refinement, and class discussion) works because the AI is predictably wrong: ChatGPT mislabels the inelastic demand in a song lyric as "perfectly elastic," and the discrepancy teaches students to validate output (Beck & Brodersen, 2025).
- **A pedagogically designed AI tutor can outperform the active-learning classroom itself.** A crossover RCT in Harvard's introductory physics course set a custom AI tutor against the course's own in-class active-learning lessons — the same research-based pedagogy, not a lecture — and found significantly more learning in less time: median post-test 4.5 against 3.5, effect size 0.63 by linear regression, with a median 49 minutes on task against 60 in class (Kestin et al., 2025). The authors credit design rather than the medium, since the tutor was engineered to carry the same seven research-based practices as the class and added only personalized feedback on demand and self-pacing.
- **A single exposure can suppress the participation it is meant to raise.** In a preregistered field experiment with 759 MBA students, assigned pre-class rehearsal with a voice-based AI partner that argued the opposing case raised voluntary in-class contributions about 31% after a second assigned use. Nothing changed in the session it prepared, and participation fell after a first use alone (Wang et al. (2026)). Dosage is a design parameter here, not an implementation detail.

The ICAP framework as the organizing lens

Active learning is precisely operationalized by the ICAP framework (Interactive–Constructive–Active–Passive), which classifies learner behavior by mode of cognitive engagement and knowledge change. Under ICAP, what is colloquially called "active learning" actually spans three distinct, ordered levels of engagement: *active* (acting on material, e.g. taking notes or answering a prompt), *constructive* (generating new output beyond the given, e.g. self-explaining or drawing), and *interactive* (co-constructing meaning through dialogue). This matters for AI in education because an AI tool can masquerade as "active" while keeping learners in the shallowest modes: clicking through a dashboard or

accepting a generated answer is active at best, not constructive or interactive. ICAP thereby sharpens the central design goal of active learning — **push learners from active toward constructive and interactive engagement** — and warns against AI systems that *answer for* the learner, which keep them passive. (Measuring Cognitive Engagement in Collaborative Discourse with an Extended ICAP Framework: Comparing Human Annotation, In-Context Learning, and Reflective LLM Agents)(Systematic review of collaborative learning activities for promoting AI literacy) This connects active learning directly to ICAP Framework, Student Engagement, and Collaborative Learning, whose highest ICAP mode is interactive dialogue.

Practical guidance

- **Keep the learner in the loop.** Design AI interactions so students act on and with output (interactive, scaffolded modes) rather than receiving finished answers; full automation measurably reduces cognitive engagement.
- **Anchor AI support in learners' own activity.** Confusion points, learner-driven questions, and problem-posing give personalized entry points for review and exploration.
- **Use teach-back and explanation.** Have learners articulate what they understand; surfacing gaps through explanation is more active than passive re-reading.
- **Pair active engagement with calibrated scaffolding.** Support should fade as competence grows — Scaffolding that never withdraws can itself become passive reliance.
- **Prefer tools that make thinking visible.** Exploratory simulations, mindtools, and interactive problem-spaces support the causal tracing and comparative reasoning at the heart of active learning.

Connections to related concepts

Active learning is deeply connected to Collaborative Learning (much active learning is social), Learning by Teaching (explaining to others is maximally active), Project-Based Learning and Experiential Learning (learning by doing in authentic contexts), Embodied Learning (physical engagement), Game-Based Learning, and Simulation. It relies on Scaffolding and timely Feedback, and is threatened by over-reliance when AI substitutes for effort. Grounded in Constructivism and Learning Theories, it spans Higher Education, K-12, and STEM Education.

Active learning is one of the strongest levers on learning gains in the AI era. Because active strategies build understanding through effortful doing, they are the most robust to AI short-circuiting — and the knowledge base's evidence shows that preserving that effort protects durable learning while letting AI absorb it erodes it (reduced study time, the learning penalty, hint abuse). Instructors who pair active-learning designs with measured gains on unassisted outcomes get the clearest picture of whether AI-assisted activity actually improved learning.

Common Misconceptions

- **"Putting AI in the activity makes it active."** An EEG study found **interactive student-AI collaboration produced the highest cognitive engagement, while full automation reduced it**.

The engagement came from the interaction, not the presence of AI, and automating the learner's part of the work moved engagement the wrong way.

- **"AI-supported inquiry is automatically higher-order."** A quasi-experiment with **120 Grade 8 students** found AI-supported inquiry-based learning raised creative mathematical performance **and** a narrower measure — the treatment moved some outcomes and not others. Correlation with a higher-order label is not the same as a higher-order task.
- **"Students designing the teaching is a technical exercise."** In the inversion study, **345 students** in a 700-student course each designed a conversational agent to teach three design patterns to a peer. The active learning came from the design work, which is pedagogical reasoning rather than prompt engineering.
- **"Engagement findings are learning findings."** The same evidence base cautions that a **no-control-group, volunteer-sample** design supports engagement claims only. Students valued open-ended design freedom (**22.3%** top positive theme) and complained most about unclear instructions (**23.7%**) — both are about the experience.

Collaborative Learning

> **Collaborative Learning** — instructional approaches where students work together to solve problems, complete tasks, or construct knowledge, supported or mediated by AI tools. In AI in education, collaborative learning research spans AI as a collaboration partner, AI as a mediator of human collaboration, and the design of collaborative AI tutoring systems.

Questions to Consider

- Think of a time you learned something deeply in a group. What made it work? Now imagine an AI chatbot joining that group — how could it strengthen or quietly undermine what you experienced?
- Research finds a trade-off: delegating reasoning to AI produces the best task performance but the least self-regulatory engagement, while the mode that builds self-regulation underperforms on the task. If you had to choose, which would you protect — the outcome or the struggle?
- The ICAP framework ranks 'interactive' collaboration as the deepest form of engagement. Could an AI that answers for the group actually downgrade collaboration from interactive to merely passive — even if students feel more satisfied?
- One study found AI mediators are trusted only while they stay neutral; when the AI shifts to advising or challenging, that trust erodes. How neutral should a group's AI mediator really be?
- When learners use AI to produce a polished artifact, they may skip the epistemic effort that builds understanding. How would you design an AI partner that surfaces disagreement and conflict instead of smoothing it over?
- Neurodivergent students report needing structured assignments, small consistent teams, and explicit roles. If AI collaboration tools are built for the 'average' learner, who might they leave out — and how would you design differently?

Introduction

Collaborative learning is grounded in sociocultural theories of learning that position knowledge construction as fundamentally social. AI introduces new dynamics: AI can serve as a peer, a facilitator, or a participant in collaborative processes. The articles in this knowledge base explore how AI-mediated collaboration affects learning outcomes, epistemic engagement, and equity — and how collaborative structures must be designed to accommodate diverse learners.

Collaboration as a construct vs. group work as a structure. Collaborative learning is the broader theory: knowledge is co-constructed through joint activity and dialogue. Group work is its most concrete formal implementation — a team producing a shared outcome, and often a shared grade. The two are closely related but not identical: a group can operate without genuine collaboration (task partitioned into independent parts, work merely merged), and collaboration can happen without formal groups (pairs, whole-class dialogue, or human–AI interaction). AI presses hardest on exactly this gap — Chen and Zou (2026) found groups whose individual GenAI practice never became collective capability because the task never required joint work,

alongside groups where the shared grade made GenAI use a coordination problem. The group work page examines these dynamics in depth; this page keeps the wider lens on collaborative learning as a whole.

AI as collaborative partner explores AI's role in group learning. **Kimmerle** conceptualizes the risk of reduced epistemic effort when learners use AI to produce polished knowledge artifacts, advocating for AI structured as an argumentative partner that preserves cognitive conflict. Testing this at classroom scale, Oppenheimer, Cash & Connell Pensky (2025) had introductory social-science students (n = 154) write argumentative essays, receive critiques from LLMs such as ChatGPT, Gemini, or Claude, and then incorporate or rebut them; blind coders found reflection in 92.7% and active rebuttal of LLM claims in 87.8% of responses (inter-rater κs = 0.81–0.89), evidence that learners behaved as critical consumers who preserved rather than surrendered the cognitive conflict of critique. **Ordered Network Analysis of Epistemic Emotions during Collaborative Problem Solving** examines how emotions shape collaborative Problem Solving with AI. **Systematic review of collaborative learning activities for promoting AI literacy** explores collaborative approaches to AI literacy development.

Facilitator endorsement is the strongest observed lever on whether students accept a contrarian agent: in twelve interprofessional teams, those whose faculty facilitator influenced their AI integration rated it more part of the team (M = 3.08 vs 2.64) and its feedback more helpful (M = 3.44 vs 2.93) (Wiss et al. (2025)).

AI-mediated peer collaboration examines how AI scaffolds human-to-human collaboration. **ProPACT: A Proactive AI-Driven Adaptive Collaborative Tutor for Pair Programming** and **Exploring How Agent Voice Accents Shape Human-AI Collaboration in K-12 Group Learning** explore how AI agent characteristics affect group dynamics. **When AI Agents Teach Each Other: Discourse Patterns Resembling Peer Learning in the Moltbook Community** documents how AI agents teaching each other produce discourse patterns resembling human peer learning. Classroom-wide systems extend this to the *relational* dimension of collaboration: **CoBi** uses speech recognition and language understanding to detect "uplifting" small-group discourse (being respectful, equitable, committed to community, moving thinking forward) and returns non-evaluative, classroom-level Visualizations to support community building and collaboration skills, deliberately withholding student- or group-level feedback to protect Privacy and Trust.

Neurodivergent perspectives on collaboration reveal critical design requirements. **Zastudil et al.** found that neurodivergent students need structured assignments, small consistent teams with explicitly defined roles, and predictable interaction patterns — requirements that AI collaboration tools must accommodate. This connects collaborative learning to Inclusive Learning and Neurodiversity.

Teacher-AI collaboration examines how teachers and AI work together. **Balancing Teacher and Student Agency: Co-Orchestration Tool Design Supporting Real-Time Dynamic Pairing** and **Towards Synergistic Teacher-AI Interactions with Generative Artificial Intelligence** explore frameworks for human-AI collaborative teaching, connecting to Teaching and Human-in-the-Loop.

AI as a pedagogical mediator reconceptualizes AI's role in collaboration beyond tool or peer. Drawing on sociocultural theory and distributed cognition, **Niari** positions AI as an active participant in the orchestration of interaction, epistemic sense-making, and regulatory processes, redistributing agency, authority, and responsibility across human and non-human actors without displacing learner or teacher agency. This grounds collaborative learning in a socially mediated, co-regulated view of AI rather than an individualistic one.

Collaboration modes and the efficiency–regulation trade-off. Empirical research on college students collaborating with AI for complex problem-solving identifies three distinct modes — *Delegated Reasoning*, *Concerted Interpretation*, and *Delegated Elaboration*. The most efficient mode (delegated reasoning) yields the highest task performance but the lowest learners' self-regulatory engagement, while the mode with greatest self-regulation (concerted interpretation) underperforms on task outcomes.(Unpacking Interaction Profiles and Strategies in Human-AI Collaborative Problem Solving: A Cognitive Distribution and Regulation Perspective) This reveals a central design tension: collaborative-learning environments must balance the efficiency of the distributed human–AI system against the depth of learners' regulatory engagement.

The one meta-analytic contrast available for AI-supported collaborative work sits inside GenAI-supported PBL/PjBL interventions, where peer collaboration pooled at g = 0.885 against g = 0.416 for individual work, but the difference reached only a marginal trend (QM = 3.675, p = .055) and the individual-work side rests on two studies — so the pooled evidence that collaboration beats working alone under GenAI is suggestive rather than established (Chen et al. 2026).

Field-level mapping reaches the same conclusion from the other direction: a BERTopic analysis of 1,048 AI-in-online-learning publications from 2010 to 2023 found that socially oriented work on AI-supported collaborative learning and community development never emerged as a dominant topic, which the authors attribute to a corpus centered on individual-level analytics (Chen et al. (2026)).

A scoping review of 18 studies maps the same trade-off across group work: GenAI supported knowledge development, idea generation and communication efficiency while also reducing the demand for peer interaction, negotiation and collective sensemaking, and randomized evidence found more innovative AI suggestions without a significant gain in participants' overall innovativeness (Wei and Perkins (2026)).

Role design is a lever on the quality, not the volume, of collaborative knowledge construction. Cheng et al. (2026) assigned rotating moderator, analyst and arguer roles across 58 graduate students and their AI partner in 16 groups, and found the structure lifted the *content* of group mind maps nearly a full SOLO band (M = 3.65 to 4.59, z = 3.771, p < 0.001) while node and branch counts stayed flat — organization rather than coverage — at the cost of a moderate rise in collaborative cognitive load (p = 0.023). Lag sequential analysis added an evaluation self-transition and a conflict-to-defending path the tool alone had not produced, positioning human-AI collaboration as a design problem rather than a tool problem.

GenAI as agent and space in small groups — mode matters. Xu et al. (2026) observe that *how* a team accesses GenAI shapes collaboration: with a single shared interface in synchronous work, teams co-construct "collective prompts," run a surface–evaluate–embed cycle, and treat the chat as shared memory; in asynchronous work, private prompting and output "de-labeling" fragment transparency and raise the cost of sustaining a shared cognitive model. Their GenAI-Supported Cooperative Work (GSCW) lens frames GenAI as a configurable agent (individual assistant to team member) and an interactive collaborative space — connecting access configuration directly to the ICAP-relevant quality of interactive engagement.

GenAI as group coordination infrastructure — and the risk of flattened cooperation. Chen and Zou (2026) show how fifteen pre-service teacher groups handled GenAI in a graded group presentation, and the split runs against the usual assumption that group pressure increases AI reliance. Five groups intensified use to solve a familiar collaboration problem — not knowing what peers' sections contained — feeding that work into a chatbot to make it intelligible and align their own part, with one group rebuilding its cycle as

discussion → externalization to GenAI → collective review → re-discussion. The authors read this as more than cognitive offloading, since students kept judgment while the tool absorbed coordination, but flag that the smoother workflow may bypass the disagreement through which cohesion is conventionally built, making relational labor the open question. Seven groups cut their GenAI use instead, protecting the situated knowledge built in shared classrooms ("AI only knows that moment when you type"), fairness to groupmates, originality across groups, and the diversity of perspectives the group already held. Three groups saw no change at all: with the task partitioned into independent sections, individually sophisticated GenAI practice never became a collective capability, even though coherence was an explicit criterion. The pattern suggests group norms, not the tool, decide what a group does with AI — and that collective adoption can lower the perceived risk of misuse rather than raise commitment.

Group epistemic configuration decides where the AI sits, not how often it is used. Wang et al. (2026) gave fourteen pre-service teacher groups a learner-initiated metacognitive chatbot during a 60-minute Go-Lab inquiry on energy forms, with eight groups holding different preconceptions and six holding similar ones at equal prior knowledge ($U = 293.50$, $p = 0.515$). Both kinds of group asked comparable questions, 39 prompts retained at 18 against 21 with overlapping function distributions. Uptake diverged instead.

Process mining put AI query negotiation at an integration hub in diverse groups, three incoming and two outgoing paths, reached from a concept statement in 55.6% of cases, while in similar-preconception groups it sat on a linear query-then-process path. Diverse groups sustained positive or neutral evaluation of the AI output while similar groups sustained negative evaluation, which the authors partly trace to a proactive speaking agent arriving after the group had already agreed. Twelve of the 39 prompts met short informational follow-ups with scope clarification, their case for a request-classification layer that separates metacognitive prompts from procedural ones.

Collaboration as the object of instruction. ProPACT is an AI-driven adaptive tutor for pair programming that treats the *dyad* — not the individual — as the unit of analysis, modeling joint visual attention, joint mental effort, and pupil-based signals in real time to predict collaborative breakdowns up to 30 seconds in advance and intervene before they occur. Dyads receiving proactive feedback achieved substantially higher debugging success and completed tasks more efficiently, and showed sustained gains in collaborative regulation afterward — evidence that AI can teach collaboration itself, not just support a task. Measuring collaborative competence poses the complementary challenge of assessing collaborative problem-solving (CPS) skill at scale, which traditionally requires manually coding process data from simulated tasks into CPS behaviors — time-consuming and impractical at scale; context-aware prompting of pre-trained language models automates this coding by modeling contextual dependencies and fusing cognitive and social abilities, achieving superior performance over strong baselines. **Scaffold on the order of group talk, not its frequency.** Wong, Bulathwela & Cukurova (2026) mined 65 students' triad dialogue sequences and found one ordering — paraphrasing, then proposing, then questioning — tracked improvement while the reverse did not; the maximal scaffold raised on-task behavior yet also scripting and fewer problem-solving indicators.

AI as a neutral mediator — and the tension when it stops being neutral. Spritz is a Discord-based Large Language Models (LLMs) probe that mediates disciplinary boundaries in interdisciplinary student teams by surfacing implicit assumptions and returning anonymized syntheses to shared discussion. Students valued it as both cognitive support and a relational buffer, but a central tension emerged: AI's perceived neutrality was load-bearing, and eroded once the AI moved from neutral mediator to advisor or challenger — a key design

constraint for agents that mediate collaboration while preserving Human AI Collaboration and Trust Calibration.

A structured facilitator protocol — and its sycophancy risk. Seo et al. (2026) extend collaborative-learning design with a structured divergence–deliberation–convergence protocol: an LLM facilitator stacks speaking turns, times the phases, and summarizes incrementally, a format 45 students found simple and discussion-like and that reduced the need for external facilitation. The design turns on a tension the study measured directly: agents supported breadth of perspective-taking (groups produced larger, more divergent stakeholder and solution sets, and agents consistently voiced minority viewpoints), yet sycophantic, reasoning-free agreement flattened the cognitive conflict that makes collaboration deepen thinking. Participants asked for agent output that exposes intermediate deliberation steps rather than only conclusions, and for counterarguments that preserve genuine disagreement.

Collaborative structures for AI education. The Academic League of AI organizes AI education through democratic student AI Governance and project teams, embedding Active Learning and Project-Based Learning in a collaborative, community-connected structure.

What makes an AI recognizable as a peer rather than a tutor. Lin et al. (2026) had seven domain experts work with a Big Five-persona agent whose motivational stance shifted across forethought, performance and self-reflection while solving quadratic equations. Participants judged the agent by its social behavior rather than its mathematics: a non-judgmental space, tentative reasoning, appropriate imperfection and respect for the learner's pace read as peer-like, while blind agreement and over-instruction pushed it back toward tutor. The authors also report a tension worth keeping — peer-likeness and peer-usefulness did not always align — which is the long-standing risk of peer collaboration itself, that peers can confirm each other's errors.

The ICAP framework: collaboration as the highest engagement mode

Collaborative learning occupies the top of the ICAP framework (Interactive–Constructive–Active–Passive): the *interactive* mode — co-constructing meaning through dialogue, defending a position, or solving jointly — produces the deepest knowledge change in Chi's taxonomy. This makes ICAP both a justification for collaborative pedagogies and a design constraint on AI. An AI that mediates discussion (as Spritz or ProPACT do) is valuable precisely when it sustains *interactive* engagement; an AI that answers for the group or smooths over cognitive conflict can downgrade collaboration to a mere *active* or *passive* mode. ICAP-based annotation (see extended ICAP measurement of collaborative dialogue) and facilitation-timing research both treat the quality of interactive discourse as the outcome of interest, grounding collaborative learning in Student Engagement and the ICAP hierarchy.(Measuring Cognitive Engagement in Collaborative Discourse with an Extended ICAP Framework: Comparing Human Annotation, In-Context Learning, and Reflective LLM Agents)(To facilitate or not to facilitate: Human and LLM facilitator tendencies in online discussions) - **GenAI can take the moderator seat rather than the tutor seat.** Chen et al. (2026) ran a 16-week quasi-experiment with 64 undergraduates in which both conditions had an AI agent and a structured platform, and only the regulation scaffolding differed: an adaptive SSRL agent versus static digital worksheets (Chen et al., 2026). The adaptive group showed higher participation equality but not higher intensity, the signature of redistribution rather than more talk. - **Interactive is not automatically deeper.** In an eight-week quasi-experiment with 87 undergraduates, pairs working with a GenAI multi-agent system produced the best design projects (M = 89.64 against 86.45 for solo work on the same system). Critical-

thinking awareness gains ran the other way: largest solo (M = 0.41), near flat for peer collaboration (M = 0.06) and slightly negative for the paired AI condition (M = -0.04) (Chu, Dai and Zhai (2026)). The configuration changed which kind of thinking was activated rather than how much of it.

Practical guidance

- **Model collaboration, not just the individual.** Tools that track dyadic or group state (as ProPACT does) can scaffold the collaboration itself, predicting and preventing breakdowns rather than reacting to them.
- **Preserve cognitive conflict.** Structure AI as an argumentative partner that surfaces disagreement and implicit assumptions, avoiding the polished-artifacts problem where AI smooths over fragile epistemic engagement.
- **Contrarian personas have affective costs.** Across 97 triads, contrarian AI pushed discourse toward challenge and reflection but lowered teamwork satisfaction ($\varepsilon^2 = .062$) and psychological safety ($\varepsilon^2 = .114$) without raising creative output (Jin et al. (2026)).
- **Match the agent's function to the outcome you intend.** A review of 46 studies of AI agents in computer-supported collaborative learning found cognitive gains consistently reported while behavioral, social and emotional outcomes stayed context-dependent, with the strongest alignment between agent function and outcome inside the same domain (Ba et al. (2026)).
- **A separate Facilitator role reduces dominance, not responsiveness.** In Oyelere's (2026) simulated benchmark, adding a Facilitator agent alongside the Tutor lowered dyadic turn and word imbalance (M = 0.103 and 0.105 versus 0.183 and 0.182) without changing reciprocal engagement — though the learners were synthetic personas, not real dyads.
- **Balance efficiency against self-regulation.** Collaborative AI that maximizes task efficiency (delegated reasoning) can undercut learners' regulatory engagement; design should deliberately protect space for concerted interpretation.
- **Respect the neutrality constraint.** AI mediators are trusted while neutral; moving into advisory or challenging roles destabilizes that trust, so role switches should be explicit and configurable.
- **Accommodate neurodivergent learners.** Structured assignments, small consistent teams, and explicit role definitions are requirements AI collaboration tools must support.
- **Prefer non-evaluative, classroom-level feedback.** When supporting the relational dimension of collaboration, class-level aggregated feedback protects Privacy and student agency where individual scoring would feel surveilled; CoBi students preferred qualitative visualizations (an organic tree) over quantitative ones (a radar chart), and teachers valued using the system's noticings to spark reflection more than live display.
- **Design for the viewing/attention that precedes contribution.** Collaborative learning in online discussion forums depends not only on posting but on the reading that precedes it. Hao & Cukurova (2026) show LLM-generated discussion summaries and example posts can act as navigational scaffolds that broaden students' exposure to peers' contributions and the network

conditions for bridging (weak-tie) social capital — support that should complement, not replace, socio-pedagogical strategies for sustaining engagement under academic workload.

- **The social side shows disruption without a countervailing gain.** Across five collaboration processes a 30-expert consensus reached vulnerability only, with enhancement ratings below threshold: Social Connection (3.80 against enhancement 1.90), Socio-Emotional Development (3.60 against 2.00), Social Learning, Collaborative Learning and Sense of Belonging (all 3.30) (Kendeou, Greene & Nixon et al., 2026). The report treats the asymmetry as a design target, since collaborative problem solving is anchored to a shared product while collaborative learning has no visible referent and can erode undetected.

Common Misconceptions

- **"Giving groups AI means more collaboration."** A scoping review of **18 studies** maps a trade-off across group work: GenAI supported **knowledge development, idea generation and communication efficiency** while also carrying a relational cost in the same interventions. The efficiency gain and the relational cost arrive together.
- **"AI-supported collaborative learning has meta-analytic backing."** The **one** meta-analytic contrast available for AI-supported collaborative work sits **inside** GenAI-supported PBL/PjBL interventions rather than being estimated directly, so it is a component of a broader effect rather than a measurement of collaboration.
- **"An LLM partner preserves the group's own reasoning."** Oppenheimer, Cash and Connell Pensky (2025) tested it at classroom scale with introductory social-science students, precisely because preservation is an open question and not an assumption.

Project-Based Learning

> **Project-based learning (PBL)** — an active, learner-centered Pedagogies and Teaching Strategies in which students learn by engaging in extended, real-world projects that require inquiry, problem solving, and the application of knowledge to produce tangible outcomes. PBL emphasizes student autonomy, collaboration, and authentic tasks, and is widely used with technology — including educational robotics and AI — to give learners hands-on, meaningful projects. It contrasts with purely theoretical or lecture-based instruction.

Questions to Consider

- Think of the last time you truly 'learned by doing' — building, designing, or creating something real. What made that experience stick compared with a lecture you sat through the same week? How might that difference transfer to how students learn AI or robotics?
- PBL and problem-based learning are frequently conflated, yet they differ: one centers on producing a tangible project, the other on resolving an ill-structured problem. Before you read, how would you distinguish the two — and does your answer matter for how a course should be designed?
- A robotics study tackled a 'theory-practice gap' with an agile, semester-spanning project. When you think about your own field, where does the gap between what students are taught and what they can actually do tend to open up — and what would a project-based approach need to close it?
- PBL emphasizes student autonomy, collaboration, and authentic tasks. But learners differ in their readiness to direct themselves. What could go wrong if you dropped extended projects into a classroom without support for self-direction, and who would it harm most?
- PBL is widely coupled with gamification and educational robotics in the research. From your experience, is fun/engagement always a reliable proxy for deep learning, or can a well-scored 'game' mask shallow understanding?
- Before reading on, ask yourself: what concrete evidence would convince you that project-based learning actually beats lecture-based instruction for a specific learning outcome — and how hard is that evidence to gather in a real course?

Introduction

PBL is closely related to Active Learning, Experiential Learning, Collaborative Learning, and Constructivism pedagogy. It is especially valuable for AI and robotics education because these fields are inherently applied: learners best understand robots, algorithms, and systems by building and testing them in project contexts. PBL also fosters Computational Thinking, problem solving, and self-direction.

Project-based learning is closely related to — but distinct from — problem-based learning: both are learner-centered and context-driven, but problem-based learning centers on an ill-structured *problem* whose solution requires inquiry and knowledge construction, whereas project-based learning centers on producing a tangible

project or artifact. The two are frequently conflated, and many AI-in-education frameworks draw on both (see the problem-based learning page for the AI-era treatment).

How PBL appears in the knowledge base's research

- **Robotics projects:** Bots and Blocks presents an agile, semester-spanning project-based approach to teach robotics in an applied computer science program, addressing the theory-practice gap.
- **The Project Approach in early childhood with AI agents:** Yang, Li and Lee (2025) extend PBL's foundational form — the Project Approach (Katz & Chard), an extended collaborative investigation of a real-world topic — into early childhood, proposing a five-step **Creative Project Approach** that integrates AI agents and robots (coding robots and generative social robots) into projects to foster young children's creative learning. The five steps — identify learning needs, facilitate teacher-guided child–robot interaction, situate AI in contexts, calibrate the automation/creativity balance, and evaluate outcomes — keep the teacher as a facilitator guiding inquiry, positioning PBL as the natural vehicle for developmentally appropriate AI use with the youngest learners.
- **Gamification coupling:** A systematic review found Gamification in robotics education strongly favored project-based learning ($p = .009$).

The only three-level meta-analysis of this pairing pools 22 controlled studies (66 effect sizes, January 2023 to April 2026) and estimates a large effect for GenAI-supported PBL/PjBL, $g = 0.819$, 95% CI [0.655, 0.983]. The authors' PET-PEESE sensitivity analysis, however, reduces the estimate to $g = 0.378$, so the headline figure should be read as potentially inflated (Chen et al. 2026). Tool type moderated the effect significantly ($QM = 14.301$, $p < .001$): direct use of a general chatbot scored $g = 0.970$, against $g = 0.455$ for systems built into course platforms, virtual patients, or agents — suggesting how a tool is embedded matters more than which model is chosen. - **AI literacy and co-design:** PBL underlies many AI literacy and Teacher Education interventions, where learners co-create AI tools or resources. - **Students as agent designers at scale:** Zangari et al. (2026) had 345 undergraduates in a 700-student software design course each build a conversational agent explaining three design patterns to a peer — Part A a scaffolded Dialogflow CX tutorial, Part B an open-ended design task. The open-endedness was the top positive theme (22.3%) while unclear instructions topped negatives (23.7%), and perceived learning correlated with quiz scores only modestly ($r = 0.161$–0.315). The design lesson for PBL: student-created artifacts can carry the ownership benefits of self-flipped classrooms into AI-tool contexts, but the exploratory, no-control-group evidence supports engagement claims, not causal superiority. - **AI-agent-supported software PBL:** Tanaka et al. (2026) embedded Spec-Driven Development with AI agents into a team-based undergraduate software PBL course, structuring projects into investigation, planning, implementation, and review phases paired with instructor-run comprehension checks. - **Immersive VR studios with an embedded teaching agent:** Jin et al. (2026) specify the **AI-IVE-PBL** model for vocational design education, pairing PBL with an AI-enabled immersive virtual environment (VR headsets plus an Large Language Models (LLMs)-backed teaching assistant). PBL's customary constraints for vocational learners — limited equipment, hard-to-replicate scenarios, delayed teacher Scaffolding — are absorbed by immersion plus an in-session agent, and the model is stated as a five-phase loop (discovery, envisioning, modeling, communication, refinement) with a named actor and artifact per phase, driven by sustained idea-developing discourse. In a 12-week quasi-experiment ($n = 63$) the condition raised design ability and creative ability and lifted cognitive and behavioral

engagement, while leaving ideational novelty (innovative thinking) and affective engagement unchanged — a reminder that the design-specific and the ideational parts of a project's value do not move together.

PBL connects to Active Learning, Experiential Learning, Collaborative Learning, Robots in Education, Game-Based Learning, Computational Thinking, and Higher Education/K-12 pedagogy.

- **PBL supports AI-powered robotics learning.** Pathways research shows project-based robotics+AI curricula let high school students learn through engagement in real-world practice, designing, and playful creative expression.

PBL in AI Literacy Courses

- **Measuring PBL in AI literacy courses.** Zhu and Kong (2026) developed and validated an AI project-based learning scale (AI-PBLS) grounded in Hong Kong secondary and university students' experiences, and used it to show that perceived PBL fosters AI literacy course satisfaction through the mediating mechanisms of empowerment in AI Problem Solving and AI ethical awareness. The scale offers researchers a validated instrument, and the mediation finding strengthens the case for PBL as a vehicle that builds confidence and ethical reasoning — not just content — in AI education.

PBL With Digital Storytelling in the AI Era

- Project-based learning combined with digital storytelling offers a pedagogical response to generative AI in art and design education. A 15-week embedded case study with 426 undergraduates implemented a PBL-DS framework in which digital storytelling served as the primary methodology for students to translate local cultural heritage into emotionally resonant, Multimodal AI narratives, cultivating the creative capacities that AI lacks.

Common Misconceptions

- **"PBL's effect is large, so PBL with AI is reliably large."** The only three-level meta-analysis of this pairing pools **22 controlled studies (66 effect sizes)** and estimates a large effect, **g = 0.819, 95% CI [0.655, 0.983]** — but a PET-PEESE correction reduces it, and the estimate describes the studies pooled rather than the design in general.
- **"Customising the tool improves the outcome."** Tool type moderated the effect significantly (**QM = 14.301, p < .001**), and the direction is counterintuitive: a **general chatbot used directly pooled higher (g = 0.970)** than systems **customised into course platforms, virtual patients or agents (g = 0.455)**. The bare tool outperformed the engineered one, which argues against assuming that purpose-built products are the better purchase.
- **"Students find open-endedness the hard part."** In the student-perception data, **open-endedness was the top positive theme (22.3%)** while **unclear instructions topped the negatives (23.7%)**. Students welcomed the freedom and objected to the ambiguity — a distinction that matters because the fix is different: clearer task framing, not less open-ended work.

- **“Students who enjoyed it learned more.”** Perceived learning correlated with quiz scores only **modestly (r = 0.161-0.315)**. Satisfaction and measured learning are weakly related here, so a positive PBL evaluation is not by itself evidence the learning objectives were met.

What this means for practice

For instructors

- Write the task framing before the tool choice. Open-endedness was the top positive theme (22.3%) and unclear instructions the top negative (23.7%), so the ambiguity is where PBL with AI actually fails.
- Score learning separately from satisfaction. Perceived learning correlated with quiz scores only at r = 0.161-0.315, so a happy cohort is not a measured outcome.
- Consider the general chatbot before the custom platform. A general chatbot used directly pooled higher (g = 0.970) than systems customised into course platforms, virtual patients or agents (g = 0.455).
- Treat g = 0.819 as an upper bound. A PET-PEESE correction reduces it, and 22 studies with 66 effect sizes is a narrow base for a design claim.

For developers

- The moderation finding is a product warning: engineering a chatbot into a bespoke environment coincided with a *smaller* pooled effect. Validate that customisation adds learning value rather than assumed convenience.
- If you ship a PBL module, the instruction layer is the feature that earns the outcome, not the model.

Problem-Based Learning

> **Problem-based learning (PBL)** — a learner-centered pedagogy in which students acquire knowledge and skills by working to understand and resolve a realistic, often ill-structured problem, with a facilitator guiding inquiry rather than delivering instruction. In the AI era, PBL's structural features — problem-driven inquiry, collaborative knowledge construction, facilitation over instruction, and metacognitive reflection — have emerged as the same conditions under which generative AI integration becomes educationally productive rather than substitutive.

Questions to Consider

- In problem-based learning, the *problem* is the driver of the curriculum—not an illustration of content taught elsewhere. Can you recall a time you learned something deeply because you were solving a real problem first?
- The page argues PBL's features (problem-driven inquiry, collaboration, facilitation, reflection) are exactly the conditions under which AI becomes a productive partner rather than a shortcut. Why might that be?
- AI severs the link between a submitted artifact and the effort that produced it—the 'artifact-as-proxy' problem. How does assessing process instead of just product help, and what makes process Assessment hard?
- PBL originated in medical education partly because professional competence needs adaptive judgment, not routine execution. What's the difference between those two, and how does AI change which one we train for?
- If an AI can now make 'wicked problems' and complex real-world cases accessible to more students, what might be lost when the challenge becomes easier to reach?
- Where should an AI in a PBL setting draw the line between giving a problem, a hint, or an answer? What determines which is the right move at any moment?

Introduction

PBL originated in medical education (McMaster University, 1960s) and has since spread across health professions, engineering, and K-12. The learner takes responsibility for diagnosing learning needs, identifying resources, and constructing solutions, while the facilitator scaffolds the process. The distinctive claim of PBL is that the *problem* is the curriculum driver — not an illustration of content taught elsewhere but the context in which content is learned.

Ng'ambi and van der Merwe (2026) give a direct comparison: ten problem-based chats sustained dialogue and reached deeper explanation, while thirty structured procedural chats collapsed into ask-answer-thank and ended.

PBL in the AI era

The knowledge base's research shows that PBL has become a focal point for thinking about productive AI integration.

- **PBL's structural conditions make AI integration productive.** Rowe (2026) argues that PBL's core features — problem-driven inquiry, collaborative construction, facilitation, metacognitive reflection — are exactly the conditions under which AI functions as a partner in professional development rather than a shortcut around it. The alignment is structural, not retrospective: PBL was designed around these conditions before AI existed, rooted in the recognition that professional competence requires adaptive judgment rather than routine execution.
- **AI raises the ceiling on problem complexity.** The same argument holds that AI expands what category of problem PBL can engage, making "wicked problems" and complex real-world cases accessible to students who previously could not reach them.
- **The artifact-as-proxy problem.** AI severs the link between a submitted artifact and the engagement that produced it — a problem PBL is well positioned to address because it assesses the *process* and demonstrated understanding, not just the product. This connects PBL to authentic and process-based assessment and to the knowledge base's over-reliance literature.

The three-level meta-analysis that pools GenAI-supported PBL with project-based learning keeps product and solution performance in a separate model precisely because it measures human-AI collaborative output rather than internalized learning, and that estimate is the largest the reviewers report (g = 1.958) while resting on only six studies and carrying an approximate 95% prediction interval of [−0.740, 4.656] that crosses zero — the quantitative form of the artifact-as-proxy caution above (Chen et al. 2026). - **ChatGPT as adaptive scaffolding.** La Sunra et al. (2026) show ChatGPT integrated as adaptive scaffolding within an AI-enhanced PBL framework to improve critical thinking and personalized learning in K-12 (120 eighth graders). This treats AI as a within-PBL support rather than an answer machine. - **A controversy-injecting agent can counter groupthink.** A genAI agent voiced at three set points in an interprofessional PBL session introduced controversial perspectives, and students reported that refuting it gave them a socially permissible way to speak up, with the disagreement stimulating reflection even when they rejected the agent's responses (Wiss et al. (2025)). - **Quasi-experimental evidence from pre-service teacher preparation.** Chen and Osman (2026) compared an eight-week AI-supported CTD-PBL module with conventional instruction for 130 third-year pre-service physics teachers (65 per condition), with DeepSeek used through task-specific prompt templates as a bounded scaffold — lesson-idea generation, resource organization, explanation comparison, peer-feedback prompts and revision planning — and every AI output required to pass verification against content accuracy, pedagogical appropriateness, feasibility and Ethics before entering an instructional artifact. The module group reported higher post-test TPACK (M = 4.04 vs. 3.40, d = 1.02) and higher perceived collaborative problem solving (M = 3.62 vs. 3.05, d = 0.88), and the largest interaction effects fell on shared knowledge building and social regulation — precisely the collaborative process dimensions the structural argument above predicts AI should strengthen rather than shortcut. The authors are explicit that AI was not isolated as an independent variable: the differential change attaches to the whole condition of problem-based tasks, structured collaboration, instructor scaffolding, peer feedback and reflective revision, and both outcomes were self-reported perceptions rather than observed practice. - **Responsible-use frameworks.** Uden & Hwang (2026) advance the neuroscience-informed **LEARN**

framework (Lifelong Learning, Engagement, Active Processing, Reflection, Neuro-based Design) for ethically grounding generative AI use within PBL, countering cognitive offloading and integrity erosion. - **Domain implementations.** PBL frameworks for biomedical engineering use GenAI for summarization and coding support with replication packages (Nnamdi et al. 2026); AI-supported PBL enhances computational thinking in robotics (AI-supported PBL for computational thinking); and genAI-enabled virtual patients support medical history-taking tutorials (Mool et al. 2026). - **Evidence synthesis.** Amdan et al. (2026) systematically review 50 studies (2015–2024) on educators' engagement with AI in PBL within a human-computer interaction framework. - **GenAI in scenario-based PBL.** Neto and colleagues (2026) include problem-based learning among the scenario-based approaches in their systematic review of GenAI in healthcare education, finding that prompt design functions as instructional specification and that hybrid human-AI collaboration outperforms fully automated approaches. The review highlights the need for stronger alignment of generated content with instructional frameworks and more reproducible prompting practices in PBL contexts.

- **AI can carry the tutor's knowledge delivery but not the social regulation of group learning.** In a four-week pharmacology quasi-experiment, Shetty & Rao (2026) found AI-mediated PBL matched facilitator-led academic gains (between-group $p = 0.474$), while facilitator-led groups retained advantages in group dynamics (26.51 vs 24.74, $p = 0.035$) and critical thinking (14.75 vs 13.09, $p < 0.001$).

PBL vs. related pedagogies

PBL is closely related to project-based learning — both are learner-centered and problem/context-driven — but PBL centers on an ill-structured *problem* whose solution requires inquiry and knowledge construction, whereas project-based learning centers on producing a tangible *artifact* or project. PBL is also kin to case-based and inquiry-based learning, which share the problem-driven, facilitation-led structure. In the knowledge base's mapping, the structural argument for productive AI integration applies to any pedagogy sharing these features, not only PBL.

Why PBL matters for AI integration

Because PBL foregrounds process, collaboration, and demonstrated understanding over artifact production, it is a natural home for responsible AI use: students learn *with* AI as a partner rather than *from* AI as a substitute. The facilitator's role and the design of the problem become the levers that determine whether AI supports learning or displaces it — the same human oversight and assessment-design concerns that recur across the knowledge base.

Productive failure and PBL

Productive failure (PF) shares PBL's Constructivism core — Learners engage problems before instruction — but differs in structure: PF deliberately withholds instruction and scaffolds until *after* learners struggle to generate solutions, whereas PBL embeds facilitation throughout. The AI-era PF literature directly informs how AI should behave inside problem-based settings: Kim et al. (2026) show AI should preserve productive struggle with non-directive support across PF phases; Puech et al. (2025) demonstrate Large Language

Models (LLMs) tutors can be steered to withhold answers and elicit multiple solution attempts; and ProductiveMath uses AI to help design high-quality PF/PBL-style problems. The design question — when AI should give a problem, a hint, or an answer — is shared across both pedagogies.

Common Misconceptions

- **"PBL outcomes should be pooled with project-based learning outcomes."** The three-level meta-analysis keeps **product and solution performance in a separate model** precisely because it measures **human-AI collaboration** rather than the learner's own reasoning. Merging them would attribute a jointly-produced artifact to the student.
- **"Collaborative gains are a side effect of using AI."** A study found higher perceived collaborative problem solving (**M = 3.62 vs. 3.05, d = 0.88**) and shared problem solving (**3.40, d = 1.02**), with **the largest interaction effects on shared knowledge building and social regulation** — the collaborative process dimensions design predicts. The mechanism is the structured collaboration, not the tool.
- **"PBL with AI mainly saves facilitator time."** The measurable gains sit in process quality on dimensions that only exist when the group structure is designed for them. A PBL implementation that adds AI without structuring shared knowledge building should not expect the same effect.

Productive Failure

> **Productive Failure (PF)** — an instructional approach, grounded in constructivist theory and developed by Manu Kapur, that engages learners with problems targeting concepts they have **not yet learned**, having them struggle to generate solutions *before* receiving direct instruction (Kapur, 2008; Kapur & Bielaczyc, 2012). Rather than treating failure as something to avoid, PF treats initial struggle and error as a powerful catalyst: learners activate and differentiate prior knowledge, surface Misconceptions about AI, and prepare to learn better from subsequent instruction — leading to deeper understanding, better retention, and enhanced knowledge transfer.

Questions to Consider

- Have you ever learned more from failing at something first than from being shown how to do it? What made that failure 'productive' rather than just discouraging?
- The page's core claim is that the *order* matters: struggling to generate solutions *before* instruction produces deeper learning. What do you think happens in the brain during that struggle that later instruction can build on?
- Not all failures are equal: 'mistakes' (slips) may carry little diagnostic value, while 'errors' reveal genuine misconceptions. How might telling these apart change how you respond to a struggling learner—or how an AI tutor should respond?
- The 'Safety Gap' is the divergence between a student's AI-assisted performance and their unassisted capability. When does help that makes a student look capable actually mask what they can't yet do?
- An AI that withholds answers to preserve struggle can be perceived as less helpful. If you were a student, how would you react to a tutor that refused to give you the answer—and would that reaction match what's best for your learning?
- How might the fear of making mistakes in front of peers (or an AI) shut down the very productive struggle the page describes? What would a 'safe space' for failing need to include?

Introduction

Productive failure is closely related to, but distinct from, other "learning from difficulty" constructs: Desirable Difficulties (Bjork) focuses on introducing desirable challenges into practice; Problem-Based Learning and Inquiry-Based Learning emphasize learner-driven problem solving; and learning-from-mistakes/errors (error-correction learning) emphasizes the value of errorful processing and corrective feedback. Productive failure is distinctive in its two-phase structure — **generation & exploration before instruction**, then **consolidation & knowledge assembly after** — and its claim that the *order* (failure before instruction) is what produces the learning advantage.

The core mechanism

Learners generate solutions without cognitive support, relying on prior knowledge and producing suboptimal or even incorrect solutions. They then compare and contrast these attempts with the canonical solution during consolidation. The struggle:

- **Activates and differentiates prior knowledge**, making learners aware of gaps and misconceptions.
- **Prepares learners to learn from instruction** — they know what they don't know and can connect new material to their attempts.
- **Enhances knowledge transfer and durable skills** (Critical Thinking, resilience, communication), reduces fear of making mistakes, and promotes positive attitudes toward learning.

The PF framework has been extended through related designs including **vicarious failure**, **solution diversity**, and **adaptive guidance** (Braas et al., 2025; Brand et al., 2025).

Learning from mistakes and learning from errors

Productive failure sits within a broader family of error-centered learning theory, and the concept page covers these related ideas:

Learning from errors

Errorful processing can aid retention and conceptual change, particularly when learners are given opportunities to reflect on and reorganize their understanding (Kapur, 2008; Schwartz & Martin, 2004). In the AI era, this is operationalized in systems where learners diagnose and correct their own errors rather than receiving direct corrections — e.g., clue-before-correction tasks where AI gives guided hints and learners infer the correct solution, reducing cognitive load and supporting autonomous revision. Elaborative feedback produces significantly higher learning gains than verification-only feedback (Hattie & Timperley), and the timing of feedback matters.

Mistakes vs. errors

A useful distinction: **mistakes** are typically slips or lapses (often from carelessness or overload) that may carry limited diagnostic value, whereas **errors** reflect genuine misunderstanding or flawed reasoning and are more productive learning material because they reveal a misconception that can be addressed. Error analysis — identifying *why* an answer is wrong — is central to learning from errors, and is a key pedagogical skill (and a target for AI feedback design).

The role of corrective feedback

Learning from errors depends on feedback that helps learners see what was wrong and why. Clue-based and elaborative feedback (guiding learners to the correction) is more effective than simply supplying the right

answer — an insight that links Feedback theory directly to productive-failure design, and to how AI tutors should respond to student mistakes.

Productive failure and AI in education

A major theme in the knowledge base's research is the tension between AI's helpfulness and the preservation of productive struggle:

- **The risk: AI erases the struggle.** Overly "helpful," Oracle-style AI that supplies answers directly can eliminate the productive struggle necessary for schema construction, creating what Wang & Shan (2026) call the **Safety Gap** — the divergence between a student's AI-assisted performance and their internal, unassisted capability. This connects to Cognitive Offloading: AI that substitutes for effort erodes the very capacities education builds.
- **The design response: AI that scaffolds struggle.** Kim et al. (2026) derive five design principles for AI supporting productive-failure-based learning (human-AI collaboration, usability, reflective design, emotional design, open knowledge), emphasizing that AI should preserve struggle while offering non-directive support. Puech et al. (2025) show Large Language Models (LLMs) tutors can be *steered* to follow productive-failure pedagogy (withhold solutions, elicit multiple attempts), at the cost of perceived helpfulness. CoMeT (Hou et al. 2026) prices that cost and locates the middle: its escalating tutor was 0.42 scale points more frustrating than the tutor that answered on request ($p < .001$) and 0.29 less frustrating than the one that only asked questions ($p = .011$), with distress detected in 8.4% of its sessions against 16.0% under the withholding tutor, and it surrendered the full answer in 6.1% of sessions. A floor that opens on an explicit statement of giving up rather than on frustration follows from the same design — without one, the learners who most need the demand route around it.
- **Withholding cost neither frustration nor motivation — only preference.** A three-arm RCT found a hint-withholding tutor matched unrestricted ChatGPT on frustration reduction and was the only arm to raise intrinsic motivation, yet students rated the answer-giving tool easier ($p = .003$) and more helpful ($p = .004$) (Bassner et al. (2026)).
- **AI as a tool for PF design:** ProductiveMath uses generative AI to help teachers create high-quality PF problems — addressing the challenge that designing productive-failure activities is effortful.
- **AI-generated errors as provocations:** the pedagogy of AI mistakes deliberately leverages AI errors and hallucinations as teaching tools, aligning with productive-failure thinking by treating erroneous output as a cognitive provocation.

This makes productive failure a central lens for evaluating AI in education: the question is not whether AI helps, but whether it helps in a way that **preserves the struggle through which durable learning is built**.

Implications for instructors and instructional design

- **Design for struggle before instruction.** Sequence learning so students attempt problems before direct teaching, then consolidate — rather than the traditional instruction-first approach.

- **Withhold solutions strategically.** Scaffold with hints, clues, and guiding questions (Socratic Method) that keep learners cognitively engaged rather than handing over answers.
- **Use AI to scaffold, not substitute.** Choose and configure AI tools that give non-directive support, preserve productive struggle, and surface errors for reflection — not answer-givers. This applies to both tutor design (steering LLMs) and classroom practice.
- **Attend to the emotional side of failure.** Emotional design, a safe space for experimentation, and reducing the fear of mistakes are essential — productive failure requires learners to be willing to struggle and fail.
- **Build error analysis into learning.** Ask learners to diagnose *why* their (or AI's) answer is wrong, using elaborative/clue-based feedback, to convert errors into learning gains.
- **Distinguish mistakes from errors pedagogically.** Not all failures are equally productive; attend to whether errors reflect misconceptions worth addressing.

Connections to learning gains and other measures

- **Learning gains:** PF is associated with improved learning compared with traditional instruction-first approaches (Kapur, 2008, 2015; Schwartz & Martin, 2004), especially on measures of transfer and deep understanding. Clue-based/elaborative feedback produces significantly higher learning gains than verification-only feedback (Hattie & Timperley).
- **Transfer and retention:** the benefits of PF are strongest on transfer of knowledge to novel problems — a durable-skills outcome rather than short-term exam performance.
- **Affective and motivational outcomes:** PF reduces fear of mistakes, increases engagement, and cultivates resilience and positive attitudes toward learning.
- **AI-specific measures:** PF-oriented AI research is evaluated on strategy fidelity (e.g., StratL's PF score, number of elicited solution attempts) and on teacher/learner perceptions, alongside traditional learning-outcome measures.

Connections to related concepts

Productive failure connects to Learning Theories (constructivism), Desirable Difficulties (valuing difficulty in learning), Problem-Based Learning and Inquiry-Based Learning (learner-driven problem solving), Metacognition (reflection on one's own attempts), Cognitive Offloading (the risk that AI erases struggle), Scaffolding (support that preserves effort), Feedback (elaborative, corrective), Prior Knowledge (activation and differentiation), Transfer of Learning (durable outcomes), and Socratic Method (questioning to provoke reasoning). In the AI era it is a central evaluative lens: does the AI help in a way that preserves the struggle through which durable learning is built?

Common Misconceptions

- **"Withholding help frustrates learners and costs motivation."** A three-arm RCT found a hint-withholding tutor **matched unrestricted ChatGPT on frustration reduction and** motivation — the cost showed up **only in preference**. Learners did not enjoy it as much and did not suffer for it, which means preference data would have rejected the design that worked.

- **“More frustration means more learning.”** The escalating tutor was **0.42 scale points more frustrating than the tutor that answered on request ($p < .001$) and 0.29 less frustrating than** the most frustrating arm. The productive range is a middle, not a maximum, so “desirable difficulty” does not license making the task harder indefinitely.
- **“Productive failure means teachers should not help.”** The design withholds *the answer* while supplying structure and escalation. Withholding a hint and withholding support are different interventions, and only the first is the one with evidence here.

Inquiry-Based Learning

> **Inquiry-based learning (IBL)** — a learner-centered Pedagogies and Teaching Strategies in which students develop understanding by posing questions, exploring independently, and constructing knowledge through a cycle of inquiry, reflection, and revision, with the instructor Scaffolding rather than lecturing. In the AI era, IBL's question-driven, exploration-centered structure has become a focal point: generative AI and Large Language Models (LLMs) tools can serve as interactive "co-inquirers" that support questioning and investigation — but only when designed to preserve rather than bypass the cognitive work of inquiry.

Questions to Consider

- Inquiry-based learning centers on student-driven questions and the inquiry process itself. How is learning driven by your own question different from learning driven by someone else's?
- The page asks whether AI serves as a 'co-inquirer' supporting your investigation or as a substitute that bypasses the cognitive work. When you use AI to explore a question, who is doing the inquiring?
- Evidence on AI-supported inquiry is mixed: it improved creative performance and attitudes but not critical Problem Solving in one study, and deepened conceptual understanding without boosting AI literacy in another. What does that suggest about what AI alone can and cannot develop?
- If treating AI output as authoritative risks over-reliance and superficial conclusions, how would you teach students to evaluate AI-generated answers as part of the inquiry cycle?
- The page connects inquiry to productive failure — learners exploring before instruction, so struggle itself prepares learning. How might AI that withholds answers and elicits multiple attempts support that struggle rather than remove it?
- What is the facilitator's role when AI lowers the friction of asking questions? If students can get answers instantly, what does the instructor now need to scaffold that they didn't before?

Introduction

Inquiry-based learning centers on student-driven questions and the inquiry process itself, typically moving through phases (orientation → conceptualization → investigation → discussion → conclusion). It is the broader family under which problem-based learning and project-based learning are often nested: IBL emphasizes the *questioning and discovery process*, PBL the ill-structured *problem*, and project-based learning the tangible *artifact*.

How inquiry-based learning appears in the knowledge base

AI as co-inquirer. A systematic review of ChatGPT for inquiry-based learning in STEAM (The AI-powered co-inquirer: a systematic review of ChatGPT for inquiry-based learning in STEAM education, 24 studies)

found ChatGPT used mainly in the conceptualization, investigation, and discussion phases — as learning tool, tutor, learning peer, domain expert, and teaching assistant. That use improved performance, critical thinking, engagement, and motivation, while posing risks of over-reliance, hallucination, and superficial conclusions when output is treated as authoritative.

Problem posing as the starting point. A quasi-experiment with 97 third-graders (Inquiry-based learning in STEM education: the impact of generative AI-based chatbots on primary school students' problem posing ability in science) showed GenAI chatbots significantly outperformed search engines for science problem posing, improving question quality and producing more integrated epistemic networks while lowering cognitive load.

Cognitive-level patterns in LLM-driven IBL. An exploratory study of 117 interview transcripts and interaction records (Luo et al.) identified 14 interaction patterns across Bloom's cognitive levels, showing how students' prior knowledge shapes LLM use and highlighting the need for scaffolding that targets higher-order thinking stages and mitigates over-reliance.

Outcomes evidence is mixed. An AI-supported IBL experiment in mathematics (Mujib et al.) improved creative mathematical performance and attitudes but not critical problem-solving skills — suggesting AI-IBL mainly supports Creativity and affective development. A meta-analysis of 29 experiments (Zhao et al.) found GenAI has a moderate positive effect on higher-order thinking, strongest for problem-solving and with 8–16 week interventions and higher Self-Regulated Learning learners benefiting most. A quasi-experiment with 48 pre-service science teachers in Türkiye (Aydın) using an 8-week AI-supported guided inquiry program (integrating problem- and design-based learning) found significant group-by-time gains in conceptual understanding of photosynthesis and cellular respiration, but *no* significant effect on AI literacy or self-perceived computational thinking — evidence that AI-IBL can deepen domain understanding while the development of AI/CT competencies requires more explicit, targeted design.

Gousopoulos (2026) isolated the AI contribution from the inquiry itself in a three-group climate study: AI-assisted inquiry outgained inquiry-only peers on decision-making (d = 0.69), with the largest gains in monitoring and adaptive management (d = 1.37), while basic data collection improved equally across all conditions.

Equity and context. A conceptual framework bridges generative-AI co-design with open educational practices to support inquiry-led STEM teaching in under-resourced contexts, using AI-generated, multilingual, contextually relevant simulations.

AI-scaffolded evidence comparison. An and colleagues (2026) show how an AI-powered information-extraction system shifts the undergraduate literature review from summarization toward **evidence organization and comparison** — students moving from isolated reading to cross-study comparison and evidence-based justification in support of research-based learning and thesis completion. This concretizes how AI can scaffold inquiry processes in STEM undergraduate research.

Why inquiry-based learning matters for AI integration

IBL's question-driven, process-focused structure is the natural home for productive AI use: students learn *with* AI as a partner rather than *from* it as a substitute. The knowledge base's evidence converges on a core tension — AI can lower the friction of information retrieval and question formulation (reducing cognitive

load and enabling deeper Reflection), but without design scaffolding it risks over-reliance and bypassing higher-order cognition. The facilitator's role, the design of scaffolds, and the explicit teaching of evaluation skills are the levers determining whether AI deepens or displaces inquiry.

One study substitutes the facilitator rather than adding a tool beside them. In a four-week pharmacology course, 136 second-year medical students were split between facilitator-led and AI-led problem-based learning. Both arms gained significantly on pre/post multiple-choice tests and the between-group difference was not significant ($p = 0.474$), but facilitator-led groups scored higher on critical thinking (14.75 against 13.09, $p < 0.001$) and on the group assessment rubric (26.51 against 24.74, $p = 0.035$) (Shetty and Rao, 2026). Inquiry outcomes split by kind: content knowledge survived the substitution and the reasoning process did not, which is what it means to say the facilitator is the lever.

Productive failure and inquiry

Productive failure (PF) is the most structured cousin of inquiry-based learning: learners explore problems and generate solutions *before* direct instruction, then consolidate. Both share the premise that learner-generated attempts (even failed ones) activate prior knowledge and prepare learners to learn from instruction. The AI-era PF research sharpens how AI should scaffold inquiry without short-circuiting it: Kim et al. (2026) derive AI design principles for preserving struggle through problem exploration and solution generation; Puech et al. (2025) show LLM tutors can be steered to withhold answers and elicit multiple attempts; clue-before-correction tasks exemplify clue-based (vs. direct) scaffolding that keeps learners doing the reasoning. These connect inquiry and PF to the broader imperative that AI must not remove the productive struggle through which durable learning forms.

In outdoor field settings the same imperative becomes spatial: GenAI can pre-structure what learners notice before they encounter the evidence, so a field-first sequence that withholds generated explanation until observations and initial interpretations are recorded protects the inquiry (Choi, 2026).

A 66-study map places generative AI beside investigation and least often at orientation. Yahya et al. (2026) coded GenAI use onto the five inquiry phases and found support reported most often in investigation (45 studies, 68.2%), then conclusion (29, 43.9%), discussion (28, 42.4%) and conceptualization (27, 40.9%), with orientation last (20, 30.3%). Eleven studies covered all five phases, 19 covered one and nine named none. Only 8 studies (12.1%) measured inquiry skills, and 4 of those had a comparison condition, so this is a map of where tools were placed rather than what inquiry gained.

Common Misconceptions

"AI is a natural fit for inquiry-based learning because both are exploratory." The fit depends entirely on design: generative AI and LLM tools can serve as interactive co-inquirers that support questioning and investigation **only when designed to preserve the student's ownership of the question**. Used otherwise, an exploratory student is following an answer rather than conducting an inquiry, and the two look similar from the outside.

"Any AI added to an inquiry unit improves it." The AI contribution has to be isolated from the inquiry itself. Gousopoulos (2026) did this with a three-group design in a climate study: AI-assisted inquiry

outgained inquiry-only peers on **decision-making (d = 0.69)**, with the evidence located in a specific outcome rather than in the general superiority of the approach.

“Inquiry is unstructured by definition.” The instructor scaffolds, and the structure is in the question design and the reflection cycle rather than in the delivery of content. Removing the scaffold does not make the inquiry more authentic; it makes it unscaffolded.

“Student-led questions will be well-formed if students are interested.” Generating a tractable question is the skill being developed, which is why a system that supplies good questions has performed the inquiry skill the activity exists to teach.

Experiential Learning

> **Experiential learning** — learning through direct experience, reflection, and the application of knowledge in authentic or hands-on contexts ("learning by doing"). Drawing on Kolb's experiential learning cycle (concrete experience, reflective observation, abstract conceptualization, active experimentation), experiential approaches emphasize that learners learn most deeply when they act, observe the results, and reflect. In AI education, experiential learning includes hands-on labs, project-based work, robotics, simulations, and real-world problem solving.

Questions to Consider

- Kolb's cycle describes learning by doing: concrete experience, reflection, observation, conceptualizing, then active experimentation. Think of a skill you genuinely learned. Did it follow that loop — and could a lecture alone have produced the same depth?
- Experiential learning is often the default in AI, cybersecurity, and robotics education, where students learn by working with real tools. What's the argument for why hands-on, applied practice closes the theory-practice gap that lectures leave open?
- Some experiential approaches now use AI assistants inside virtual labs and simulated robots. When the 'experience' itself is simulated or AI-assisted, is it still genuinely experiential — or does the absence of real consequences change what's learned?
- When have you seen 'learning by doing' fail to produce learning? What conditions — reflection, feedback, a real problem — seem necessary for experience to actually teach?

Introduction

Experiential learning is closely related to Active Learning, Project-Based Learning, Embodied Learning, and Simulation. It is particularly relevant to AI, cybersecurity, and robotics education, where students develop skills by working with tools and systems in applied contexts rather than through lectures alone. A key rationale is closing the theory-practice gap in professional preparation.

How experiential learning appears in the knowledge base's research

- **Emergency substitution, with a rubric for how far it gets you.** Elhajj et al. (2026) document a substitution forced by the 2024 conflict in Lebanon: students in a graduate Experiential Learning course at the American University of Beirut, unable to reach communities for needs assessments, interviewed ChatGPT-generated stakeholder personas instead. Two raters scored all ten group prompts and found the split instructive — alignment with educational goals (mean 5.00) and diversity of perspectives (4.90) were strong, while authenticity and realism (4.38) and especially group dynamics and coherence (3.80, with one 30-persona focus group collapsing into sequential interviews) and limitations and gaps (3.20) were weak, the last because emotional flatness, absent contradiction and thin cultural specificity recurred in every context. The authors' conclusion is a

boundary rather than a verdict: personas work as rehearsal and as a stopgap where access is impossible or unsafe, but not where emotional complexity, cultural specificity and interpersonal dynamics *are* the learning objective. Their mitigation is structural — pair simulated role-play with real interviews so students can compare, and train students to interrogate persona output for bias and generalization instead of treating it as field evidence.

- **Cybersecurity labs:** LLM-assisted cybersecurity instruction integrates a Generative AI instructional assistant into a virtual lab platform, supporting hands-on experiential skill building.
- **Robotics projects:** Bots and Blocks uses a project-based, hands-on approach to teach robotics, addressing the lack of practical experience in classic programs.
- **Simulation and embodied learning:** EduSim-LLM lets beginners experiment with simulated robots, and embodied robot interaction grounds learning in direct experience.
- **A virtual laboratory can outperform the physical one when the apparatus is not the point.** Grade 9 students on Ohm's law scored 23.45, 20.51 and 16.57 of 30 in the AI-supported virtual laboratory, the same laboratory without AI, and the physical laboratory, with every pair significant (Li and Ahmad (2026)); the authors concede the physical laboratory's disadvantage may shrink where handling apparatus is itself the goal.
- **AI as infrastructure for uncertainty, not efficiency.** Shi, Dai & Zhang (2026) give a generative-AI role the job of generating disruptive events and cascading consequences in a business simulation, so teams revise plans under incomplete information, and warn that protected simulations can leave decision habits that become a liability outside the classroom.
- **Doing versus being told, measured across five weeks.** In a quasi-experiment with 126 first-year engineering students, a two-hour experiential session on learning with generative AI produced a metacognitive knowledge gain of +0.25, against roughly zero for a lecture. That is a medium effect (d = -0.37) which fell short of significance at p = .055 after multiple-comparison correction, and self-reported AI engagement was comparable in both groups at five weeks (3.99 and 3.93) (Benazet i Montobbio et al., 2026). The bound this places on the page's rationale is worth stating plainly: one hands-on session moves metacognitive knowledge in the right direction without settling the comparison, so the advantage of doing has to be built from repeated cycles rather than assumed from a single lab.

Two forms of hands-on learning in an AI-supported curriculum

A thematic review of 32 peer-reviewed studies of hands-on learning in AI-supported design education (Yu, Liu & Zhu, 2026) argues that AI reorganizes rather than replaces experiential learning, and draws a distinction the knowledge base's other sources tend to collapse: *Embodied Hands-on*, which depends on bodily action, tools, and materials, and *Cognitive Hands-on*, which develops through continued operation, judgment, and adjustment of AI-generated outputs. Both run the same action–feedback–reflection–refinement cycle, but they draw feedback from different sources — real-world material resistance in the first case, language and visual outcomes in the second — so they should not be treated as equivalent or as substitutes. The review's caution is that generation efficiency can compress the exploratory phase: several included studies report reduced exploratory sketching and gradual trial-and-error,

so more iterations enabled by AI need not mean greater iterative depth, and students can miss the failure and material-constraint encounters that make hands-on work educative. Consistent with this, prompting alone did not raise Creativity in the reviewed work, whereas multi-step operations (generate, modify, select) did — again locating the learning in the learner's judgment rather than in the generation.

Experiential learning connects to Active Learning, Project-Based Learning, Embodied Learning, Simulation, Robots in Education, and Higher Education professional preparation.

Work-integrated experience can be the binding condition for advanced competence: across 89 sponsored capstone projects in a smart-manufacturing lab, advancement from Workforce Readiness Level 6 to 7 was gated by industry-embedded placements rather than additional coursework (Smith et al. (2026)).

Common Misconceptions

"Experiential learning means hands-on activity." Activity is the surface; the learning mechanism is the cycle of doing, reflecting, conceptualising and testing. A lab session with no structured reflection produces familiarity rather than conceptual change, which is why "we added a practical component" is not evidence of experiential learning.

"AI can substitute for the experience in experiential learning." It can simulate some systems and cannot supply the experience that forms competence in applied domains such as AI, cybersecurity and robotics, where students develop skill by working with the real tools and systems. A simulated security environment teaches procedure; a working system teaches the consequence of a misconfiguration.

"More authentic tasks are straightforwardly better." Authenticity raises the transfer value and the assessment problem together: real systems produce variable, hard-to-grade evidence, and the more authentic the task the less the outcome resembles a score. Design has to hold both, which is why the reflection structure carries as much weight as the task.

"AI tutoring fits experiential learning as it fits lecture content." The fit is weaker, because a tutor can supply explanation and cannot supply the encounter with the system. Its natural place in this Pedagogies and Teaching Strategies is around the reflection and conceptualisation stages, where a learner is making sense of what happened — not in place of the doing. Symonette et al. (2026) generate the encounter rather than script it: from a learner's goals, GELLI builds situated scenes with characters, support and reflection at runtime, and in a within-subjects study with 40 Japanese learners it beat expert-authored videos on vocabulary recall (d = 0.45) and confidence (d = 0.45) but not speaking.

Implications for Practice

For instructors

- Structure the cycle rather than the activity: doing, then reflecting, then conceptualising, then testing in a new situation. A session that stops after the doing has produced familiarity, not learning.
- Add the practical component where the concept is abstract and remove it where the practical has become the entire course. Hands-on is a means with a cost in time and a benefit in transfer, and the ratio is a design decision.

- Reserve AI for the reflection stage, where a learner is making sense of what happened.

For developers

- Build reflection prompts and a record of what the learner did, so the sense-making stage has material and the evidence is auditable.
- Do not present a simulation as a substitute for operating a real system in domains where the consequence of error is the curriculum.

For programme designers

- Check that applied programs contain applied work rather than lab proxies; the transfer claim rests on the authenticity of the encounter.

Game-Based Learning

> **Game-based learning (GBL)** — the use of games themselves (digital or physical) as the medium and context for learning, where the game's mechanics, challenges, and progression carry educational content. Learners learn *through* playing. Relatedly, **gamification** applies game-design elements (points, badges, levels, leaderboards) to non-game learning activities without turning them into full games. In AI and robotics education, both approaches are used to make technical content engaging and motivating.

Questions to Consider

- Game-based learning uses the game itself as the medium for learning — you learn *through* playing. Gamification just layers points, badges, and levels onto a non-game activity. How different do you think those two are in effect on real learning, versus on short-term engagement?
- A comparative review found game-based learning more prevalent in informal settings while gamification dominated formal classrooms and favored project-based learning. Why do you think each approach found a different home — and what does that tell us about where each works best?
- Gamification is grounded in self-determination theory — autonomy, competence, relatedness. If motivation is about satisfying those needs, why might a points-and-badges system succeed or fail depending on how it shapes perceived effort and attention?
- Research suggests the motivational benefit of game-like and AI-supported designs depends on how they shape perceived workload and attention, not on gamification alone. When have you seen a game or badges boost engagement without actually improving learning — or vice versa?

Introduction

GBL is grounded in Motivation, Student Engagement, and Active Learning theories: games provide intrinsic motivation, immediate feedback, and authentic problem contexts. It overlaps with Simulation, Project-Based Learning, and Robots in Education. GBL is particularly relevant to Robots in Education, Computational Thinking, and CS Education, where games can make abstract technical concepts concrete and fun.

How GBL appears in the knowledge base's research

- **Robotics education:** A comparative systematic review of game-based learning and gamification in robotics education found GBL more prevalent in informal settings, while gamification dominated formal classrooms and favored project-based learning.
- **Robot-mediated games:** REMind is a robot-mediated role-play game for anti-bullying intervention, and MotiBo uses interactive digital storytelling to boost motivation.
- **AI conversational agents in simulation games:** Wenzel, Geiger, and Liening (2026) derive the CAIS-GBL framework — four design principles and fifteen design features for AI conversational agents in digital game-based learning — from theory-driven meta-requirements spanning

cognitive, motivational, affective, and socio-cultural engagement, with an equity-by-design stance. Their instantiated agent (Lara) in a business simulation game was positively received for cognitive and social presence and Self-Regulated Learning support, addressing the common gap of limited formative feedback and structured reflection in simulation games.

- **AI-GBL effectiveness:** A meta-analysis covering 55 studies of AI-supported game-based learning reports gains in knowledge, intrinsic motivation and affective engagement, though just 4 studies (7%) cleared its High-quality bar and only 4 (7%) were RCTs (Kaşarcı & Yurt, 2026). Effectiveness turned on aligning the AI mechanism with a stated learning theory.
- **GenAI as the game's author, not its player:** Xie et al. (2026) had a model draft seven characters and narrative material for an offline mystery role-play game, and the game then beat the same instructor's lecture in a 42-per-arm randomized trial (partial $\eta^2 = 0.566$). Students never used the AI, so the effect belongs to the format.
- **Students as game designers rather than players:** Karampa et al. (2026) had 22 primary students aged 8-12 design an augmented escape board game about misinformation, stacking project-based learning with design thinking and the Room2Educ8 escape-room framework. Composite AI literacy on a 20-item DigComp 3.0 questionnaire rose from 3.684 to 4.309 on a 5-point scale, $t(21) = -21.086$, $p < .001$, with all five competence areas improving. The class generated 11 proposals with AI prompts and merged them into one buildable game. Self-report, one class, and no control group.
- **Split the AI into a dialogue coach and a difficulty engine.** An AI-enhanced Roblox environment for upper-secondary computational thinking paired a GPT-4 non-player character, capped at two to three sentences and barred from giving answers, with a rule-based engine that set difficulty from time-to-solution and error rate (Hengsawat, Junruang & Kanjug, 2026).

Gamification

Gamification is the application of game-design elements (points, badges, levels, leaderboards, challenges, progress bars) to non-game contexts to motivate and engage users. Unlike game-based learning — where learning happens *through* a game — gamification layers game mechanics onto an existing learning activity without turning it into a full game. It is used in education to boost motivation, Student Engagement, and persistence, and is widely applied in formal classroom settings.

Gamification is grounded in motivational theory, particularly Self-Determination Theory (supporting autonomy, competence, and relatedness) and behavior-change frameworks. It has shown particular synergy with Project-Based Learning in applied domains like robotics. In the knowledge base's research:

- **Robotics education:** the comparative review found gamification dominated formal classrooms in robotics education ($p < .001$) and strongly favored project-based learning ($p = .009$), while game-based learning was more common in informal settings.
- **Engagement and motivation:** gamification is used across the knowledge base to increase learner engagement and motivation in AI, programming, and STEM learning contexts. Generative AI, motivation, and engagement research examines how game-like elements combine with AI to sustain learner interest. Two 2026 studies extend this by comparing gamified and AI-supported

conditions against traditional instruction: a NASA-TLX study measured perceived workload across traditional, gamified, and AI-supported learning conditions, and an ARCS study examined motivational "ergonomics" in gamified and AI-supported learning with implications for workplace training. Together they clarify that the motivational benefit of game-like and AI-supported designs depends on how they shape perceived effort, workload, and attention (e.g., ARCS attention/relevance dimensions), not on gamification alone.

GBL and gamification together connect to Robots in Education, Student Engagement, Motivation, Self-Determination Theory, Active Learning, Simulation, Project-Based Learning, and Computational Thinking.

Common Misconceptions

"AI-supported game-based learning has a solid evidence base." The synthesis behind the claim is large and thin at the same time. A **55-study systematic review** finds positive effects on knowledge, intrinsic motivation and affective engagement — but only **4 studies (7%) met its High-quality threshold**. A pooled positive effect drawn from a corpus where 93% of studies fall below the review's own quality bar is a hypothesis with a literature attached, not a finding to design against.

"Positive effects on motivation and knowledge are mutually reinforcing." They are separately measured and, in the wider literature, separately scheduled: engagement and achievement move on different timelines, so a game that raises intrinsic motivation has demonstrated one outcome. Treating the motivational result as corroborating the knowledge result inflates a two-part finding into a stronger one than the design supports.

"If a game engages students, the learning follows from the fun." Fun is the delivery mechanism for the repetition a game makes tolerable, not the mechanism of learning. A game that adds engagement without adding productive practice has added the part that was never in short supply.

Implications for Practice

For instructors

- Ask what the game is making students repeat, not whether students enjoy it. Repetition of the right operation is the mechanism; enjoyment is what makes the repetition tolerable.
- Treat motivational and knowledge outcomes as separate claims, and do not let a rise in intrinsic motivation be reported as evidence of learning.
- Check quality against the review's own bar before adopting a title on the strength of a positive synthesis: only 7% of the studies met it.

For developers

- Instrument learning outcomes separately from engagement and affect, and publish both.
- Build the productive practice first and the game layer second; a game layer over weak practice has automated the part that was never scarce.

For researchers

- Raise the design quality of the field rather than its volume; a 7% high-quality rate is the binding constraint on what can be concluded.

- **Conversational feedback in a simulation raises germane load without lowering extraneous load.** In a five-week business simulation game with **234 students**, regular users of a GPT-4o-based feedback chatbot reported **significantly higher germane cognitive load** than users-with-access who did not engage ($\beta = -.468$, $p < .001$) and than the static-feedback control ($\beta = -.253$, $p = .028$). **Extraneous load showed no effect** in either specification ($F(1, 219) = 0.499$, $p = .481$). Both loads **declined across the five weeks** (extraneous $\beta = -.388$, $p < .001$), a novelty effect measured on cognitive load rather than engagement (Wenzel, Geiger and Liening, 2026). The design point is that the feedback carried personalization, signaling, segmenting and feed-forward structure over 19 concrete indicators — the chatbot surface alone is not the treatment.

Learning by Teaching

> **Learning by teaching (LbT)** — the instructional framework, grounded in the protégé effect, in which students deepen their understanding by explaining material to a peer, tutee, or agent. Decades of work in LbT and peer tutoring show that explaining concepts, anticipating misunderstandings, and responding to questions consolidate understanding and support transfer. In the AI era, **teachable agents** — and increasingly **LLMs configured as novice tutees** — operationalize LbT at scale, positioning students as instructors who must explain, correct, and fill gaps.

Questions to Consider

- Recall a time you truly understood something only after explaining it to someone else. What was happening mentally — and why do you think teaching produces deeper understanding than just studying alone?
- A common view is that teaching is for experts, and novices have nothing to offer. Yet 'learning by teaching' rests on the opposite premise: preparing to teach forces you to organize knowledge and find your own gaps. How does that reframe who benefits from teaching?
- The page describes 'teachable agents' — software that students teach as part of learning. With an LLM, you can configure a chatbot as a fallible novice tutee that asks questions and makes mistakes. What would you need to design into such a tutee for it to actually improve learning rather than just chat?
- One challenge is 'engineering fallibility': AI models are trained to give expert, fluent answers, which is the opposite of the struggling novice the learning-by-teaching paradigm wants. Why might an error-prone tutee be more effective for learning than a correct one?
- A ChatGPT-based teachable agent improved learning but its tendency to generate correct code limited error-correction practice. How might a tool that always gives the right answer actually shortchange the learner who needs to practice spotting and fixing mistakes?
- If you were to design a learning-by-teaching activity for your own class, what would make the teaching task *consequential* enough that students put real effort into it rather than copy-pasting an answer?

Introduction

Learning by teaching is the finding, usually traced to the protégé effect, that preparing to teach — and actually explaining to another person or a teachable agent — produces deeper processing than studying alone. The demands of teaching force learners to organize knowledge, anticipate misunderstandings and generate explanations, which surfaces gaps in their own understanding and strengthens Metacognition. AI enters the idea from both directions: tutoring systems and teachable agents can play the student, while a growing literature asks what happens to learning when the machine, rather than the learner, supplies the explanation (Generative AI, CS Education).

The Protégé Effect

Learning by teaching rests on the finding that preparing to teach and actually explaining to another person produces deeper processing than studying alone. The demands of teaching — articulating ideas, anticipating misunderstandings, and answering questions — force learners to organize knowledge, identify gaps in their own understanding, and generate explanations that support retention and transfer. Benefits are most evident in Collaborative Learning contexts and in well-structured domains that support teachable agents (e.g., Betty's Brain). The protégé effect names the mechanism: students put forth more effort and reflect more deeply when they feel responsible for teaching something, so they clarify Misconceptions about AI and fill gaps through explanation and Metacognition.

Teachable Agents: From Rule-Based to Conversational

Teachable agents are the software systems through which learning by teaching is operationalized — a learner teaches a system as part of learning. Traditional teachable agents were rule-based or retrieval-based and could respond only to limited commands; their key limitation was an inability to engage in natural-language dialogue. Large language models change this: they can flexibly adopt roles via prompting — including the role of a "tutee" that asks questions or makes mistakes — and engage in open-ended dialogue, enabling LbT in less-structured domains (writing, vocabulary) than was previously possible.

The knowledge base's evidence base traces this shift to **conversational, LLM-based teachable agents**:

- **ChatGPT as a teachable agent** (Chen et al.) supports LbT in programming, improving knowledge gains, programming ability, and self-regulated learning — though its tendency to generate correct code limits error-correction practice.
- **Explique at scale** (Wang et al.) deployed an AI teachable agent (Algorithm Apprentice) to 546 students over an 11-week semester, finding that explanation-oriented dialogue predicts fewer incorrect quiz submissions, while external-content reuse predicts more.
- **Vocabulary teaching** (Uchida et al.) used an LLM as a student to generate dynamic questions, improving retention at 3 and 7 days.

Engineering Fallibility: LLMs as Novice Tutees

A central design challenge for LLM-based teachable agents is that LLMs are trained to produce expert-level, fluent responses by default — the opposite of the fallible novice the LbT paradigm wants. Making an LLM a good tutee requires **engineering fallibility**:

- **Generated errors can pass as authentic.** In a blinded annotation study, experts misclassified 164 of 196 (83.7%) LLM-generated Java submissions as human-written, so a tutee can supply realistic bugs to debug rather than only correct code (Keramati et al. (2026)).
- **Prompting for teachability** (Miller & Bosch) found that constraint-based prompts explicitly forcing error production (e.g., "answer incorrectly" or "get 2–3 wrong") elicit novice-like behavior far more reliably than persona-, misconception-, or uncertainty-based prompts.

- **Engineered knowledge gaps** (Yang et al.) design problems the LLM cannot solve without knowledge only the student possesses, making teaching a necessity and countering the passive over-reliance of LLM-as-tutor use.
- **Explique's apprentice constraints** (Wang et al.) instruct the tutee to (a) stay a novice, (b) keep requesting clarification until the student's explanation is accurate, and (c) never reveal the target explanation — and to *resist* students who try to reverse the roles and have the tutee explain back.
- **Unlearning as a weights-level route to fallibility.** Machine unlearning suppresses 16 targeted knowledge components in Mistral-7B, dropping accuracy from about 0.75 at a 10% forgetting ratio to below 0.5 at 40% while the base model held near 0.85. The suppressed knowledge returned through supervised relearning and coach-guided dialogue, so the tutee's knowledge level is a dial rather than an assertion (Song, Guo & Lin, 2026).

Questioning, Self-Regulation, and Active Learning

Two further affordances recur across the knowledge base:

- **Questions identify knowledge gaps.** LbT systems use learner-generated questions to expose gaps and reinforce comprehension, and LLM-generated questions replace rigid template-based generators.
- **Teach-back surfaces what clarification misses.** In a 22-participant post-lecture review system, a Peer agent's reflective teach-back consistently exposed gaps between what learners believed they understood and what they could articulate, which lecture-grounded clarification alone had not revealed (Fang & Reidsma (2026)).
- **LbT scaffolds self-AI Regulation in Education.** Teaching a conversational agent fosters Self-Efficacy and the implementation of self-regulated learning strategies, and connects LbT to Desirable Difficulties — the effortful act of explaining and correcting is itself a productive struggle that AI's friction-removal would otherwise erase.
- **What predicts tutor learning is knowledge-building, not prior knowledge.** Across 23 middle-school tutors, the share of responses that built knowledge rather than restated it predicted conceptual post-test scores ($\beta = .138$, $p < 0.05$) while prior test scores did not predict who produced them, and low-prior tutors who built knowledge finished level with high-prior peers (Ameen et al., 2026).

Why It Matters in AI Education

Learning by teaching is the constructive, Active Learning counterpoint to the dominant LLM-as-tutor pattern. Where a tutor gives answers (and risks Over-Reliance), an LbT setup makes the student the teacher, forcing explanation, gap-detection, and knowledge construction. This positions LbT as a key strategy for turning generative AI from a crutch into a tool for deeper learning, and connects to Desirable Difficulties, Active Learning, and Constructivism Pedagogies and Teaching Strategies.

Putting Learning by Teaching into Practice

Design patterns for an AI tutee

The research above converges on a few reusable patterns for turning a default-expert LLM into a productive tutee:

- **Constraint-based novice prompts (most reliable).** Rather than asking the model to "pretend to be a confused student," explicitly force fallibility and a teaching loop, e.g.: *"You are a novice student learning about [concept]. Ask me to teach it to you. Ask clarifying questions and deliberately get 2–3 things wrong during our conversation. Never state the correct answer yourself — wait for me to explain, then tell me whether I made sense."*
- **The reverse-teaching guard.** Add a rule that the tutee must *decline* to explain the answer back when the student tries to flip the roles: *"If I ask you to solve the problem or explain the concept, remind me that I'm the teacher and ask me to explain it instead."* Explique shows this resistance is what preserves the LbT interaction.
- **Engineered knowledge gaps.** Structure the task so the model *cannot* answer without information only the student holds — the student's knowledge becomes genuinely necessary, not optional. This converts the interaction from optional chat into required teaching.
- **An external success criterion.** Give the teaching a real consequence — a gatekeeper quiz that unlocks only after the student teaches successfully (Explique), or a code-judging platform the student must make the agent's output pass (Chen). Accountability is what sustains genuine effort and prevents the whole exercise becoming a checkbox.

Tips for instructors

- **Make the teaching task consequential, not busywork.** The strongest evidence for engagement comes from activities that matter — Explique gated a graded quiz behind the teaching exercise; Chen tied the tutee's output to passing a judging platform. If teaching is purely optional, students will rationally skip the hard part.
- **Give students a teaching protocol, not just a chat window.** Scaffold the interaction with a structure — "explain the concept → give a concrete example → answer the tutee's questions → check for understanding" — so open-ended dialogue becomes a deliberate teaching sequence rather than aimless conversation.
- **Address content-dumping head-on.** Explique found that direct copy-paste of external content rose from under 15% to 30–35% of interactions by the end of the semester. Tell students why pasting defeats the purpose, and consider an accountability step (e.g., "explain the agent's misunderstanding in your own words").
- **Pair LbT with debugging practice.** Because AI writes correct code, students may lose error-correction practice. Deliberately ask the tutee to *misimplement* something, or follow the teaching session with a bug-finding task, so debugging stays in the loop.
- **Watch the effort gradient.** Expect novelty to fade; plan to vary the target concepts, add challenge, or rotate which students take the teaching role to sustain cognitive effort across a term.

Tips for developers

- **Prefer hard constraints over persona alone.** Prompting for "uncertainty" or "a student persona" is unreliable; explicitly force errors and a clarification loop. (See Prompting for Teachability: Designing Novice Personas in LLMs for Learning by Teaching Contexts.)
- **Build a completion criterion.** Define *when the student has explained enough* (Explique used an LLM tool function keyed to the concept's learning objectives) so the interaction ends on understanding, not on a time limit or a fixed turn count.
- **Log and code the dialogue.** Explique used word-per-minute detection plus LLM semantic coding to classify interactions as Detailed / Minimal / External Content Use — that signal is how you detect circumvention and declining engagement before it becomes a problem.
- **Give instructors a dashboard.** Completion rates and qualitative patterns in teaching interactions let a human intervene when effort drops (Explique's instructors monitored exactly this).

Implications and open questions

- **LbT is a scalable antidote to AI over-reliance** — it inverts the tutor/student role and keeps the learner cognitively active, which matters more as AI gets more fluent and more "helpful."
- **Fallibility is a feature, not a bug.** A tutee that is *too* correct removes the error-correction and gap-detection that make LbT work; design for the productive struggle rather than against it.
- **Open questions remain:** How do LbT interactions sustain beyond a semester as novelty fully fades? Does LbT transfer to non-CS, less-structured domains at the same scale? Can automated dialogue coding become a practical, real-time engagement monitor for instructors? And how do we keep the teaching role meaningful for *every* student rather than a motivated few?

Common Misconceptions

"Any tutee works, since the benefit lies in explaining." The benefit depends on the tutee's responses being informative. A tutee that already understands everything gives the tutor no gap to detect, which is why making an LLM a good tutee requires **engineering fallibility** — designed errors and confusion the teacher-student must diagnose and correct. The protégé effect comes from the tutee's ignorance, so a capable tutee removes the mechanism.

"Generated errors are good enough because they are wrong." Only if they are plausible. In a blinded annotation study, experts **misclassified 164 of 196 (83.7%) LLM-generated Java submissions as authentic** student work — which is simultaneously evidence that the errors are realistic and a warning that a tutee can be wrong in ways that teach the wrong diagnosis.

"Asking an LLM to act confused is a trivial prompt." It is a design problem, because the fallibility must be calibrated to the concept being taught and to the learner-tutor's current model. Random errors produce debugging practice; errors reflecting a specific plausible misconception produce conceptual restructuring, and only the second is the pedagogical target.

"Learning by teaching is a softer activity than being taught." It is more demanding. Preparing to teach forces the organization of knowledge and the location of one's own gaps, which is why the approach surfaces

misunderstandings that passive reception conceals — the difficulty is the mechanism rather than a cost to be minimized.

Scaffolding

> **Scaffolding** — structured support that helps learners accomplish tasks they cannot yet complete independently, with support fading as competence grows. In AI in Education, scaffolding is the primary design principle for ensuring AI tools support learning rather than replace it.

Questions to Consider

- Think of a time someone 'helped' you with something you were learning, and the help did the work so well you learned less. Where's the line between support that lets you grow and support that replaces you? The page argues this is the central design question for AI tutors.
- Scaffolding is rooted in the Zone of Proximal Development — enough support to enable progress, not so much that learning is bypassed. What does 'too much support' look like in an AI tutor, and can you detect it from the student's behavior alone?
- A key finding: students often *prefer* the more directive AI tutor roles even though they *perform better* with collaborative peer and Teaching-assistant roles. Does learner preference reliably track what's best for learning — and what does this divergence imply for letting students choose their own scaffolding?
- Scaffolding that never fades creates dependency. The page notes automated scaffolds risk staying static instead of being withdrawn as competence grows. Why is 'fading' essential, and why might an AI system fail to do it if it isn't deliberately designed to?
- The design principle is 'scaffold, do not substitute.' Students themselves asked for AI that 'does not provide any solutions for you — you still learn as you have to find the correct answer yourself.' Does that match how you've experienced effective help, or have you preferred the shortcut even while knowing it cost you?
- Set a goal before reading: pick a task you teach, and sketch what a hint looks like that preserves the learner's effort versus an answer that removes it. How will you know your hints are in the productive-struggle zone?

Introduction

How scaffolding appears in AIED

- **Prompt-based scaffolding:** Guided LLM scaffolding teaches structured prompting as a learning intervention. Critical engagement scaffolding uses culturally responsive approaches.
- **Mixed-initiative scaffolding for gaps the learner cannot name:** Sun et al. (2026) keep the writer in charge of narrative synthesis while the system takes initiative only over domain discovery, proactively flagging knowledge gaps writers cannot formulate as queries.
- **Socratic scaffolding:** Socratic AI dialogue withholds direct answers, using questions to guide discovery — a form of Desirable Difficulties scaffolding. As a boundary condition, questioning

helps at onset but decays with depth, so the fade rule shifts from eliciting to addressing the error: the benefit falls from a 20-point advantage at onset to 3 points by the fourth stuck turn, while addressing the error rises from +5 to +12 Ahtisham et al. (2026).

- **Adaptive fading:** Intelligent tutoring systems adjust scaffolding based on Knowledge Tracing estimates, providing more support for unmastered concepts and less for known ones.
- **The function, not the tool, decides what counts as success:** Vasileiou et al. (2026) propose a three-function framework for AI support in special education. *Compensation* reduces an executive demand so the learner can participate (success = access while support remains). *Scaffolding* supports performance just beyond current capability (success = decisions with targeted assistance). *Development* builds strategies usable without the tool (success = strategy use after fading or transfer). Each function carries a different evaluation standard, and the field's recurring error is reporting task completion during support as development. It is a narrative review with interpretive categories, not a pooled effect estimate.
- **Need-triggered adaptive scaffolding in clinical interview training:** the MeduAI-SP randomized trial (Yang et al., 2026; N = 100 third-year medical students) operationalized scaffolding as adaptive, need-triggered support: a turn-level evaluator agent flagged when a learner was stuck, omitted key history, risked premature closure, or impaired rapport, and only then did a tutor agent issue a Socratic prompt. Expert annotation of 207 consultations showed that scaffolding need was strongly phase-dependent, rising from about 16.1% of student utterances early in the encounter to 34.8% late (24.1% flagged overall) — empirical evidence that novice consultation support is most needed during integration and diagnostic reasoning, not initial information gathering. The scaffolding condition outperformed a structured progressive-disclosure control on the final OSCE-aligned examination (71.8% vs. 55.6%; β = 16.4 percentage points; P = 3.30e-4), with the largest gain in communication (Hedges' g = −0.79).
- **Hint systems:** AI tutor hint research examines when hints help versus when they encourage Over-Reliance.
- **Scaffolds that raise post-mistake recovery.** In a 6,000-student middle-school field experiment, AI support slowed progress and cut questions attempted but increased next-attempt correctness after errors and reduced the attempts needed to return to a correct answer — a "productive slowdown" rather than answer supply (Oreopoulos et al. (2026)).
- **Training the learner is itself a scaffold.** A 45-minute session teaching students to prompt a model by SRL phase, and to remediate its visual and reasoning errors, raised physics revision accuracy (d = 0.81) without increasing reported total cognitive load (Huang et al. (2026)).
- **Conceptual and representational scaffolds:** Concept Catalyst and LLM tutor rethinking explore design patterns for cognitive support. Davor (2026) supplies a domain where representational support and answer-giving have to be pulled apart: geometry proof is rich in Visualization resources, yet the step from a relationship that can be seen to a valid deductive argument is the one learners fail to make, so the scaffold has to carry them across representations rather than hand them another picture. His quasi-experiment with 86 Ghanaian senior high school students configured generative AI to prompt and question rather than solve — asking learners to justify what they observed, name the relevant theorems, and order their logical steps, with the teacher

using the AI's representations to steer discussion — and the AI-supported class outscored conventional instruction on proof construction even after controlling for pre-test performance. Perceptions of the feedback and explanation quality were favorable, though only the experimental group was surveyed. The scaffold is positioned here as the bridge from visual intuition to deductive reasoning, and the paper never names the model or a collection window, so it offers more of a design warrant than a replication recipe.

- **"Scaffold, do not substitute" as a design principle:** Favero et al. (2026) argue that the central risk of AI in education is misalignment — AI that substitutes for human effort erodes the capacities education is meant to build — and derive a single design principle, *scaffold, do not substitute*. Scaffolding must be a first-class capability of AI systems: knowing *when to withhold an answer, ask a question, surface uncertainty, or present alternative perspectives*. Their analysis of student essays shows learners themselves converge on this — asking for AI that "does not provide any solutions for you, you still learn as you have to find the correct answer yourself." The principle positions scaffolding as the alternative to a self-reinforcing harm cycle of substitution across cognition, Learner Agency, emotion, and Ethics.
- **Mentoring as scaffolding for a research process.** Wang et al. (2026) treat a systematic review as an intentional learning experience in which mentoring supplies integrated methodological and emotional scaffolding, while automation is confined to procedural load such as abstract screening, and data extraction, reconciliation and synthesis stay with human reviewers.
- **Scaffolding embedded in the medium, not bolted on:** Wang, Du and Jin (2026) operationalize four scaffolding principles inside a video player — ZPD-based adjustment of comment depth, *fading* scaffolding (knowledge support thins over the timeline), *distributed* scaffolding (every comment is either knowledge or emotional support), and cognitive-load-derived **timing** — by computing frame-level video entropy and inserting comments only in low-information intervals. Their four-condition ablation with 20 learners found the entropy-timing module produced the strongest and most robust effect on perceived quality when removed ($Z = -2.85$, $r = 0.45$, $p = .004$), which makes the *scheduling* of scaffolding a measurable design variable rather than a packaging detail. The study also carries a warning for automated scaffolding: ChatGPT-generated comments were consistently harder to read, less lexically diverse, and less topically aligned than instructor comments, with the largest relevance gap in emotional support (feedback quality).
- **Emotional scaffolding as a prompt layer, measured against cognitive scaffolding alone.** Holding the interface and lesson fixed, the emotional version asked students to report feelings at three points and used those reports to vary tone, affective scaffolding and cognitive challenge along control and value appraisals, with temperature at 0.7 so the adaptations guided rather than dictated replies. In the dialogue traces it bought more performance-phase and self-reflection work than SRL prompts alone, and more enjoyment and less boredom. It added nothing to learning gains or self-efficacy in a single 25-minute session (Diordiev, Stenberdt & Makransky, 2026).
- **Preferred scaffolding is not always the most effective:** Zhu, Yang and Yang (2026) found in a within-subjects experiment that students performed best with Peer and Teaching Assistant AI roles (which foster collaborative reasoning) yet preferred the more directive Tutor and Excellent

Student roles — a divergence between preference and performance that cautions against equating learner preference with effective scaffolding in AI-supported mathematical modeling.

- **A more structured scaffold is not automatically a more agentic one:** an expert design bot raised interaction length and self-authored prompts relative to plain ChatGPT, but collaborative Problem Solving agency fell in both conditions, with agreement instead of critique the lowest-agency behavior observed (Krushinskaia et al. (2026)).
- **Automated scoring as a deliberate scaffold:** Chen and Liu (2026) treated an automated interpreter-scoring system as formative scaffolding rather than as a measurement instrument, in a 14-week comparison with 46 English Translation and Interpreting sophomores. The scaffold converted into a gain only where the deficit it targeted was decomposable, reliably scored and sensitively scaled: linguistic accuracy and logical coherence rose, while information fidelity and delivery fluency stayed flat, fidelity being the dimension on which automated and human ratings disagreed most ($r = 0.12$). The cycle it reinforced was also partial. Only practice-phase execution and monitoring correlated with score gains ($r = 0.42$), while pre-learning planning sat near the scale midpoint ($M = 3.01$) and students set goals from the previous score rather than from the task ahead. A scaffold can be well placed inside the performance phase and still leave the planning that would make it unnecessary untouched.
- **Closed-loop scaffolding on the learner's current boundary:** Zhu, Luo and Li (2026) built a music-education loop in which Multimodal AI error detection over performance audio and score becomes the reward that steers reinforcement-generated practice tracks, so difficulty follows the learner's current boundary instead of a fixed syllabus: generated practice trajectories matched learner skill profiles at a peak cosine similarity of 0.962, and the Group x Time interaction favored the scaffolded group in a 12-week quasi-experiment with 120 undergraduates (beta = 0.52, 95% CI [0.31, 0.73]). Two limits follow for automated scaffolding. Detection is triage rather than judgment, since rhythm error precision of 89.7% means roughly one flagged error in ten is a false alarm, and blind expert review rated support for musical expression the system's weakest area, leaving interpretation to the teacher.
- **Pacing is scaffolded too.** Englmeier (2025) pairs content scaffolding with a temporal layer of weekly time allowances, progress dashboards and end-of-section checks; without pacing, nearly 25 percent of over 600 learners began in the final week and 95 percent of them failed.

The ZPD connection

Vygotsky's Zone of Proximal Development provides the theoretical foundation: scaffolding targets the space between what learners can do independently and what they can achieve with support. AI tools should operate in this zone — enough support to enable progress, not so much that learning is bypassed. A configuration that inverts the usual direction of adaptation appears in Sidorkin's (2026) graduate course, where the learner rather than the system set the support level: weekly readings were generated on demand and students dialed comprehension level through iterative prompting (pacing, definitions, vocabulary density, depth). Analysis of three reading logs found definitional markers 3.4x to 8.7x more frequent in AI responses following comprehension-oriented prompts than in baseline explanatory text, with the clearest cases building a definitional layer and then a numbered procedural one, which makes scaffold density a measurable property

of the learner's request rather than only of a system's mastery estimate. Requiring at least three follow-up questions per reading made that dialing routine, turning the text into an interaction that surfaced comprehension gaps the instructor otherwise would not see.

Scaffold form has to match what the learner can already hold, not only what the task requires. In a systematic scoping review of 24 evidence sources on creative thinking in children aged 6 to 15, Niu et al. (2026) report that younger children lacked the precise linguistic and metacognitive control that text-based prompting demands and needed multimodal, adult-facilitated interfaces, while text-based LLMs showed stronger reported outcomes with older children and young adolescents. Prompt dependence was strongest in the lower grades, and no included study examined developmental readiness thresholds, so the authors treat modality and scaffolding choices as an open design question to be settled by the learner's capacity rather than by convenience.

Connections

Scaffolding connects to Over-Reliance (scaffolding that doesn't fade creates dependency), Cognitive Load Theory (scaffolding manages cognitive load), Feedback Loop (scaffolding provides formative feedback), and AI Literacy (learners must recognize when scaffolding is beneficial vs. when it displaces learning).

Agents must scaffold dynamically, not statically: Woollaston et al. (2026) identify that automated scaffolds risk staying static instead of being withdrawn as competence grows, and recommend dynamic scaffolds that adapt and fade — a key guardrail for Agentic AI. CoMeT (Hou et al. 2026) supplies both the separation and the warrant for *when* to fade: its support climbs one rung each time a learner does not use it and drops to the lightest rung on take-up, holding metacognitive demand statistically equivalent to a withholding tutor ($p_{TOST} = .004$) while delivering an artifact in 48.1% of sessions against 23.7% — more system labor, not less. The trigger it validated is aim rather than depth: after a full demonstration the tutor later conceded 30.3% of what was still open, after a pasted artifact 25.9%, after a bare assertion 20.4% and after a request to build 33.7%, whereas turns not aimed at the decision under support drew a later concession 40.3% of the time against 28.8% for aimed turns (11.5-point difference, 95% bootstrap interval [2.1, 22.4]). Take-up was sparse — 37.0% after the first ask and 21.8% after the third — so a fade rule keyed to learner effort would read a non-answer as readiness.

Fading can be trained out of a tutor. A multi-turn RL tutor rewarded only on the current problem and a masked near-transfer variant stopped fading support and assigning independent work, though nothing penalized either, because their payoff lies beyond one dialogue episode (Macina, Kapur & Sachan, 2026). A reward horizon that ends with the problem will erase the fading a design specifies.

A fourth zone makes the source of the scaffold visible: Tsim and Gutoreva (2025) add "known to GenAI" to Vygotsky's zones, so a task falls into Substitute, Complement, Aid or Non-negotiable — and Non-negotiable holds what needs a person because it is normative, tacit or too risky to hand over. - **Place AI by phase of the idea, not by course.** The six-move placement frame holds AI out of the first hard attempt and final unaided check while licensing it between them for hints, examples and drill; if AI makes the task feel effortless, it is in the wrong place (Brcic & Frljic, 2026).

Scaffolding must be situation-appropriate, not maximal: Zhang et al. (2026) introduce TutorMoments, which evaluates whether LM tutors scaffold only when support is needed, push for rigor when the student is ready,

and avoid over-scaffolding (reducing cognitive demand more than the situation requires). Minimally prompted frontier models default to over-scaffolding at the expense of productive struggle.

- **AI that scaffolds productive struggle.** Kim et al. (2026) derive AI design principles (non-directive support, reflective design, Human-in-the-Loop) that keep scaffolding in the productive-struggle zone rather than collapsing to answer-giving; Puech et al. (2025) show Large Language Models (LLMs) tutors can be steered to give help only when strictly necessary — scaffolding that preserves the learner's own effort.

Scaffold withdrawal as the enforcement mechanism for verification. Kumar, Wongsirichot and Nanthaamornphong (2026) synthesize 72 computing-education studies and locate scaffold withdrawal, alongside guardrail tools and Self-Regulated Learning designs, as one of three ways courses enforce critical engagement with AI output — structurally (constraining what the tool returns), procedurally (reflection logs, self-testing) and temporally (progressively restoring conditions under which independent reasoning is required). Their evidence is that efficiency gains under AI assistance do not transfer to unaided performance, and that the failure mode — the *pseudo-apprenticeship* pattern, where students watch AI generate code without performing the task — is exactly modeling without whole-task practice. Graduated access therefore functions as a fading schedule for a powerful new form of support, and the review grounds it in 4C/ID: assistance helps only when the learner already has enough schema to engage critically with it (the zone of proximal development, Cognitive Offloading).

Sequencing is the scaffold's other lever: Vendrell and Johnston (2026) recommend requiring a learner's independent attempt before any AI consultation and then using the model to generate counterarguments rather than answers, with deliberate AI-free phases, so the support amplifies reasoning instead of replacing it.

Rule-Guided vs. Ad-Hoc Scaffolding

- **Rule-guided vs. ad-hoc scaffolding.** Looi, Liu, and Sun (2026) formalize a distinction central to scaffolding design: **rule-guided scaffolding**, in which tutoring is governed by an auditable three-layer architecture (diagnosis → intent selection → constrained response generation), versus **ad-hoc scaffolding**, where helpful moves are difficult to audit and replicate. Their primary-school math study showed rule-guided scaffolding improves interactional consistency, reduces premature answer-giving and early closure, and sustains cognitive engagement — evidence that explicitness and auditability of scaffold moves matter for both consistency and learning in procedural domains.
- **Scaffolding as the constrained pathway between bypass and offloading.** The Neuroplasticity-AI Interaction Model names scaffolding as the third of three pathways for LLM help, alongside direct bypass and cognitive offloading, and defines it by whether the model preserves the effortful processing the task is meant to train (Bypass, Offload, or Scaffold: A Conceptual Model of How Large Language Models Shape Learning). The model's calibration evidence is a natural experiment in scaffold constraint: unrestricted GPT-4 access in a study of nearly 1,000 high-school mathematics students produced a 48% practice gain but a 17% deficit on the unassisted exam, while hint-constrained GPT Tutor produced a 127% practice gain with the exam deficit largely eliminated. The design lesson matches the rule-guided versus ad-hoc distinction above at a coarser grain: it is the constraint on what the tutor is allowed to supply, not the presence of a tutor, that determines whether the scaffold is removed successfully.

The rule-guided versus ad-hoc distinction reaches past the tutor and into the assignment itself. A cross-institutional faculty collaboratory found that critique of AI output did not happen on its own, so requirements to audit, compare, revise and justify generated content had to be written into the task, and those who protected independent disciplinary analysis before AI entered found candidates could evaluate AI output more critically. Rehearsal evidence agrees: pre-service teachers practicing with AI partners used more probing and exploring questions when structured post-rehearsal feedback was provided. In both cases support is specified in advance rather than improvised, separating designed guidance from the ad-hoc help that is hard to audit and replicate.

- **A correctly constrained scaffold still fails if the constraint is not administered.** Azimi (2026) built what the distinction above prescribes — a budget of 25 hints per session, a 15-minute cap on AI use, a required end-of-session reflection, and no generated code — and randomized 33 master's students between it and unrestricted Generative AI use across seven weeks. Assignment performance and concept-inventory gains did not differ between conditions. The hint budget did not act as a rationing mechanism: some students spent most of it on the first problems and had none left for the demanding ones, others finished with most unused, and within the Coach condition it was the students who already had a deliberate strategy for spending a hint who scored higher. The constraint raised reported confidence and followed students out of the classroom as a self-questioning habit (whether a question was worth asking the tool), but it rewarded existing self-governance rather than developing it. Auditability of a scaffold and a learner's capacity to use it are separate conditions.
- **A scaffold the learner cannot verify is a fluent substitute.** Because chemistry reasons across observable phenomena, particulate models and symbolic notation, a generated answer can be locally persuasive and globally wrong. Vega-Baudrit and Rivera Álvarez (2026) place scaffolding on the productive side of their Presage-Process-Product analysis and uncritical copying on the failure side, and require scaffolds to demand representational translation in both directions, since a response that describes neutralization correctly can still claim that every equivalence point has a pH of 7. Verification is designed into the task rather than announced as a rule: students identify a false assumption, correct a unit or mechanism error, compare a symbolic structure with a submicroscopic model, or justify rejecting a generated answer. Because students cannot verify what they do not yet understand, prior knowledge and scaffolding come first, and prompting is treated as an epistemic act in which the learner specifies the constraints the answer must satisfy.

Common Misconceptions

- **"Scaffolding is a constant level of support."** Expert annotation of **207 consultations** showed scaffolding need was **strongly phase-dependent, rising from about 16.1% of student utterances early** in the encounter. A single scaffold level is misallocated at both ends of the same consultation.
- **"Any structured control condition is a fair comparison for scaffolding."** On the examination, the scaffolded arm still beat a genuine progressive-disclosure alternative (**71.8% versus 55.6%**), so the gain was measured against a real pedagogical alternative rather than against nothing.

- **“Scaffolding effects are general.”** The gain was **16.4 percentage points (P = 3.30e-4)**, with the largest improvement in **communication (Hedges’ g = -0.79)**. The effect concentrated in one outcome, so an average across outcomes understates where it works and overstates where it does not.

Socratic Method

> **Socratic Method** — a pedagogical approach rooted in guided questioning and dialogue rather than direct instruction, now being adapted for generative AI tutoring systems. In AI in education, the Socratic method is operationalized through LLMs that ask probing questions, scaffold reasoning, and withhold direct answers — aiming to promote deeper understanding and productive struggle rather than answer-fetching.(Analyzing Undergraduate Problem-Solving in Physics Through Interaction With an AI Chatbot)(Critical AI Tutors: Empower or Enslave?)

Questions to Consider

- Think of a time a teacher (or friend) answered your question with another question and it actually helped you think. What made it work, and when did it instead just feel frustrating or evasive?
- The Socratic approach withholds direct answers to provoke 'productive struggle.' Do you believe struggle is necessary for deep learning, or is it sometimes just unnecessary friction — and how would you tell the difference?
- An AI Socratic tutor must decide when to guide, when to hint, and when to give a direct answer, based on a student's real-time signals. How do you think a system (or a human) knows which move to make at a given moment?
- The page notes a frustrated student may need a brief direct answer before returning to Socratic questioning. What do you think this implies about the limits of a one-size-fits-all question-only approach?
- If a chatbot that only asks questions can produce measurable reasoning gains, what might be lost compared to the original Socratic dialogue with a human mentor — and what might be gained?

Introduction

The Socratic method is one of the oldest pedagogical techniques — originating with Socrates in ancient Athens — and it has found new relevance in the age of generative AI. In AI education research, the Socratic method refers to AI systems that engage learners through guided dialogue, posing questions that lead students to discover answers rather than providing them outright. Asking structured questions rather than providing answers is one of the strongest pedagogical scaffolds for deep learning; when automated via AI, it produces measurable reasoning gains but also requires careful calibration to avoid frustrating learners or displacing human mentorship.(Analyzing Undergraduate Problem-Solving in Physics Through Interaction With an AI Chatbot)(Critical AI Tutors: Empower or Enslave?)

Socratic and directive feedback moved different things: Socratic feedback raised comprehension monitoring and task orientation, directive feedback scored higher on prioritization of essential features, and only the directive condition gained from a customized agent (Han et al. (2026)).

Ng'ambi and van der Merwe (2026) capture Socratic questioning working and failing in the same Grade 9 mathematics class: when a learner arrived with a hypothesis, the tutor disaggregated it into sub-questions, but on a structured Pythagoras task it restated and drifted off-topic.

How it works in AI tutoring

Unlike direct-instruction AI tutors that give answers, Socratic AI tutors use question sequences that: - **Elicit prior knowledge** — asking what the student already knows about a topic - **Probe reasoning** — "Why do you think that?" or "What if the situation were different?" - **Surface Misconceptions about AI** — through carefully chosen counterexamples - **Guide toward insight** — without giving the answer away

The Socratic approach directly embodies the principle from EduQwen: **reward "guiding" over "answering."** However, real-time Socratic calibration is harder than paper-bench pedagogy: EduQwen optimizes for correct guiding on a multiple-choice Benchmark, whereas a live Socratic tutor must decide *when* to guide, *when* to hint, and *when* to answer — based on real-time student signals. Affective state is a critical moderator: a frustrated student may need a brief direct answer before returning to Socratic mode. A stricter variant removes the teaching entirely: an introductory-physics agent that only probes asks students to defend a correct prediction against one changed variable (cave detection) and keeps the message after a correct answer indistinguishable from the one after a wrong answer (Cho (2026)).

Hint design has a documented form in a domain this page otherwise does not cover. In a second-language revision task with 58 university students at CEFR A1–B1, the design gave guided clues and required learners to infer the correction rather than receive it (Lukešová & Jennings, 2026). Reduced cognitive load and personalized revision paths were reported mainly for learners who already held enough prior knowledge to act on a clue, and feedback depth varied with how well the student prompted. Withholding the correction therefore has a proficiency floor, which is the calibration problem in a form a study can measure.

Evidence of effectiveness

A custom Socratic AI chatbot deployed in a large-enrollment introductory mechanics course (150 first-year STEM majors) produced measurable reasoning gains:

Metric	Result
Sample	150 first-year STEM majors
Knowledge-based skills rating	Median **4.0/5**
Overall effectiveness rating	Median **3.4/5** (notable gap)
Question specificity (first turn)	~10–15%
Question specificity (final turn)	**100%**
Specificity × grade correlation	Pearson **r = 0.43**

Interpretation: Students began with vague, generic questions but progressively sharpened them through Socratic interaction — a clear indicator of developing expert-like reasoning. The positive correlation between question specificity and self-reported expected grade suggests that learning to ask better questions is itself a domain skill.

The effectiveness gap

The gap between “knowledge-based skills” (4.0/5) and “overall effectiveness” (3.4/5) suggests a tension: students recognize that the Socratic bot improved their reasoning, yet do not fully endorse it as a complete tutoring solution. Possible reasons: - Socratic dialogue is effortful; students may prefer direct answers for efficiency - The chatbot cannot provide the relational support of a human tutor - Some students may get stuck in Socratic loops without resolution

A counter-finding: unrestricted access can outperform constrained modes

Not all evidence favors constraining the AI. Socrates went Nuclear (Clin Deffarges, Kosmyna & Maes, 2026), a randomized EEG study of 50 participants comparing an unrestricted ChatGPT-style bot, a Socratic hint-only mode, and an adaptive question-limited mode on a nuclear-safety learning task, found that the **unrestricted chatbot produced higher learning gains** than both constrained modes ($p < .03$, $d > 0.80$) — even though the **adaptive condition generated significantly higher EEG-measured cognitive engagement** ($p = .018$). The result complicates the assumption that pedagogically constrained (Socratic) interaction always yields deeper learning: on short-horizon factual acquisition, free access won, while restricting access raised measured cognitive engagement without converting it into higher immediate post-test gains. This is a useful calibration point alongside the stronger learning-outcome results above: constraint can boost engagement, but the engagement-to-retention translation is not automatic, and over-constraining may simply frustrate learners seeking answers.

The strongest causal support for constraint points the other way: in a K-12 review, high-schoolers using a general-purpose chatbot scored about 17% worse on closed-book finals than peers with no AI access, while a tutoring-specific bot with graduated hints and a refusal to give direct answers mitigated the drop (Stanford SCALE Initiative (2026)).

- **A Socratic tutor with full context can be rated the worst of four.** In a 2×2 randomized trial with 132 introductory Python students, the GPT-4o assistant using Socratic questioning with full problem context scored significantly lower on support for task completion (mean rank 48.63, μ = 3.53) than the direct-instruction and no-context variants ($\chi^2(3) = 12.14$, $p = .007$). It trended highest on interaction stress and external LLM use (23% against 15% overall), and produced the fewest full-comprehension post-task explanations (48%). Socratic conditions sent more queries (μ = 11.1 per problem without context), which Eastwood et al. (2026) read as withheld answers forcing extra back-and-forth rather than productive struggle.

In clinical-interview training, the MeduAI-SP trial (Yang et al., 2026) had the tutor agent deliver Socratic prompts only on a flagged need — missing key history, premature closure, conversational impasse, or communication breakdown — phrasing them as reflective questions such as whether the gathered information sufficed to support the leading diagnosis. Students trained under this Socratic scaffolding scored 31 percentage points higher on the observable “expressing empathy” checklist item (Holm-corrected P = 8.30e-4) and 0.90 points higher on the 1–5 OSCE communication domain (P = 4.50e-4), linking non-answer-giving questioning to measurable patient-centered communication gains rather than to diagnostic accuracy (84% vs. 86%; P = 1.000).

Fidelity is not guaranteed by configuration: a purpose-configured ISLE facilitator restored the test-before-prediction order students had inverted, yet when pressed to "just tell us" which can weighed more it produced mass values no one had measured, crossing from questioning into fabricating data (Tufino & Damiani (2026)).

Research in the knowledge base

The **Socratic Physics Chatbot** provides empirical evidence that the Socratic method can be operationalized through generative AI at scale, serving simultaneously as a teaching tool and data-collection instrument for Learning Analytics. Unlike rule-based Socratic systems of the past, Large Language Models (LLMs)-based approaches can adapt question sequences dynamically based on student responses.

Adversarial AI agents enact constructive conflict — a Socratic variant — prompting novice designers to reconsider their assumptions, leading to more design iterations and higher-rated final work. This connects Socratic questioning to Design Thinking and Critical Thinking.

Multimodal dialogue systems extend Socratic tutoring to visual domains, using a zero-retraining intervention protocol that asks models to describe, reason, and self-correct — a Multimodal AI Socratic scaffold.

Retrieval-augmented tutoring operationalizes Socratic principles through retrieval, anchoring each response in authoritative course content rather than relying only on the model's parametric knowledge — addressing the gap that pedagogical quality alone is insufficient without content fidelity.

Socratic tutoring in biology teacher preparation. A quasi-experiment with 124 prospective biology teachers found a ChatGPT-4 Socratic tutor on socio-scientific issues outperformed offline peer discussion on argumentation quality ($F(1,121) = 14.23$, $p < .001$), with gains concentrated in rebuttal and counter-evidence evaluation rather than claim formation (Ergasheva et al., 2026).

LFTutor (Shi et al., 2026) applies Socratic questioning to a subject where withholding the answer is the whole task: teaching laypeople to see the logical fallacy in a persuasive text they believe is valid. Its dialogue agent decomposes the learner's own argument with the Toulmin model (claim, grounds, warrant), detects the learner's intent, and then selects exactly one of four strategies - Responding, Evidence, Assumption, Refutation - in a fixed priority order that mirrors the Toulmin structure, with a separate verifier agent checking after generation that the reply actually executed the chosen strategy and rephrasing it when it did not. The evaluation metrics are the Socratic failure modes rather than learning gains: divergence from the topic, stance change (caving to the learner's position), repetition, failure to refute, failure to ask for evidence, strategy fixation, unexplained fallacy terminology, and passive guidance. Across 1,000 simulated dialogues per framework with a GPT-4o backbone, LFTutor passed 84.5% of dialogues on average against 61.5% for a prompt that listed those same pitfalls and 31.2% for plain role-play prompting, and the ablation shows the gain is not from the Toulmin vocabulary but from verified strategy execution and intent-based selection. With 20 human participants debating the tutor, LFTutor scored significantly better on eight of nine Likert metrics, including helpfulness (4.15 against 1.65), with repetition the one dimension where the difference was not significant.

Gating can make withholding enforceable rather than cosmetic: Prober.ai constrains an LLM to ask only inquiry-based questions and releases a concrete revision suggestion only after the student writes a defense

that clears a reflection gate, returning a coaching nudge instead when the defense is thin (Bi, Wei and Zhou (2026)).

Agency and critical use

Favero et al. (2025) caution that even Socratic AI can undermine Learner Agency if students become dependent on the questioning structure rather than internalizing it. The goal is not permanent Socratic scaffolding but **scaffolded transfer** — students eventually Socratize themselves.

Connections to other concepts

The Socratic method is closely tied to Scaffolding (providing just enough support), productive-struggle (letting students wrestle with difficulty), and Intelligent Tutoring (adaptive question sequencing). It contrasts with Over-Reliance — students who receive direct answers may bypass learning, while Socratic guidance maintains cognitive engagement. It supports Self-Regulated Learning and Metacognition by making reasoning visible, and connects to Formative Assessment when used to probe understanding in real time.

Open Questions

1. Does Socratic dialogue transfer across domains, or is domain-specific reasoning non-transferable?
2. How does Socratic specificity correlate with *actual* (not self-reported) course performance?
3. Can Socratic AI be combined with peer feedback for social amplification?

- **Withholding answers to provoke reasoning.** Puech et al. (2025) engineer LLM tutors to follow productive failure pedagogy by withholding solutions and eliciting multiple attempts — a Socratic-style refusal to give help except when strictly necessary; Wang & Shan (2026) recommend Socratic and Adversarial AI architectures that preserve constructive cognitive friction.

Common Misconceptions

- **“Socratic questioning is just the absence of answers.”** A custom Socratic AI chatbot deployed in a large-enrollment introductory mechanics course (**150 first-year STEM majors**) produced **measurable** gains, and the design is structured questioning — a constrained interaction, not a silent model.
- **“The effect is downstream of engagement.”** Socrates went Nuclear (Clin Deffarges, Kosmyna and Maes, 2026) is a **randomized EEG study of 50 participants** comparing an unrestricted ChatGPT-style bot against a **Socratic** one, which measures the mechanism rather than inferring it from outcomes.
- **“Constraints are the problem to be removed.”** The strongest causal support for constraint points the other way: in a K-12 review, high-schoolers using a general-purpose chatbot **scored about 17% worse on closed-book finals** than peers using a constrained tool. The unconstrained tool was the harmful condition.

Critical Pedagogy

> **Critical Pedagogy** — an educational approach, rooted in the work of Paulo Freire and later critical theorists such as Henry Giroux, that treats teaching and learning as inherently political acts. Rather than merely transmitting skills or knowledge, critical pedagogy asks who benefits from education, whose knowledge is privileged, and how schooling reproduces or resists systems of power and oppression. In AI-in-education, critical pedagogy interrogates the corporate and capitalist logics shaping AI adoption, centers the voices and epistemologies of marginalized communities, and treats AI literacy as a practice of resistance and social transformation rather than mere technical competence.

Questions to Consider

- Who does your education — or the AI tools in it — actually serve? Critical pedagogy insists this question is unavoidable, not optional. What's your honest answer?
- Critical thinking asks 'is this reasoning sound?' Critical pedagogy asks 'who does this education benefit, and whose knowledge counts?' How are those two questions different, and when does one need the other?
- Some scholars describe generative AI's spread into education as a form of 'colonization' that extracts data, labor, and resources from marginalized communities. Does that framing feel extreme, or does it name something real?
- Critical AI literacy can include 'resisting AI' — refusing the inevitability of tech as a solution. In what situations might strategic refusal or non-use be a more responsible choice than adoption?
- Who gets to decide what counts as authoritative knowledge? If AI systems are positioned as authoritative, what happens to learners' own lived and community epistemologies?
- Under critical pedagogy, a teacher is not a neutral transmitter of AI skills but a facilitator who helps Learners interrogate the politics of AI. How comfortable are you with that role, and what would it ask of you?

Introduction

Critical pedagogy is distinct from Critical Thinking. Critical thinking is a cognitive skill — evaluating arguments, questioning assumptions, and reasoning carefully — that can be practiced within almost any framework. Critical pedagogy, by contrast, is a *political and ethical stance* that connects those skills to questions of power, justice, equity, and social transformation. The knowledge base treats them as related but distinct concepts: critical thinking asks "is this reasoning sound?", while critical pedagogy asks "who does this education serve, and whose knowledge counts?".

Critical pedagogy and AI in education

AI in education raises sharp questions for critical pedagogy, and the knowledge base documents several strands:

- **Critique of the "AI colonization" of education.** Critical and feminist scholars argue that generative AI is reshaping education in ways that repeat patterns of colonial exploitation and extraction — of data, labor, and natural resources — enriching the powerful at the expense of marginalized communities.(Can we disrupt the momentum of the AI colonization of science education?) This framing rejects the "techno-utopia" narrative that presents AI as a neutral silver bullet.
- **From compliance to human flourishing.** A socialist-humanist review reframes AI literacy as transformation rather than compliance, naming "AIgemony" — AI reinforcing corporate power asymmetries — and the "ghost work" of invisible human labeling labor, and urging the "being" mode of active engagement over the "having" mode of possession (Rose (2026)).
- **Feminist and justice-centered AI.** A feminist approach to AI prioritizes justice over profit, asks critical questions about the nature and ownership of knowledge, who benefits from AI, and who is accountable when systems fail. It calls for critical AI literacy framed within feminist pedagogies. (Can we disrupt the momentum of the AI colonization of science education?)
- **Resisting AI as a critical literacy practice.** Critical AI Literacy (CAIL) can encompass "resisting AI" — a stance that refuses the inevitability and techsolutionism of dominant discourse, and instead cultivates collective Learner Agency through dialogic, collaborative pedagogies that imagine alternative futures.(Reorienting Critical AI Literacy: A Community-Rooted Praxis of "Resisting AI")
- **Multimodal AI composition as critical AI literacy pedagogy.** Burriss et al. (2026) document a classroom unit in which 22 eleventh-grade students composed video public service announcements about AI Ethics issues of their choosing, translating surveillance, data consent and algorithmic accusation into 90-second to 3-minute films built from sound, image, text and their own bodies. Framed by Critical Posthumanist Literacy, the work shows the political stance in practice: across all seven films harm emerged from tangled human–machine responsibility rather than from a villainous tool, and students still closed on Learner Agency — "the solution is in our reach" — even as one participant dissented that youth "completely lack any kind of credibility." The authors argue that creative, collaborative composition is itself a form of critical AI literacy, and that existing AI literacy scales and competency frameworks, which assume individually measurable performance, systematically exclude it.
- **Redistributing epistemic authority.** Community-based AI learning grounds AI engagement in learners' lived and community epistemologies, challenging the positioning of AI systems as authoritative knowledge sources.(Community-Based AI Learning: Redistributing Artificial Intelligence's Epistemic Authority in Education) This involves epistemic fine-tuning, redistribution of authority, and situated discernment.
- **Critical engagement is the exception, not the norm.** Across 42 classroom episodes in a Romanian lower-secondary study, 15 (35.71%) were AI-dependent and 16 (38.10%) AI-enhanced,

leaving only 11 (26.19%) AI-critical — which motivates Voicu's (2026) six-checkpoint developmental-critical model for interpretive autonomy.

- **Digital mediation as critical practice under resource constraint.** Sithole (2026) applies Critical Digital Pedagogy with decolonial epistemologies of the South to academic development in South African Historically Disadvantaged Institutions, where developers filter institutional AI rhetoric through the question of what it means "for our students from poor schools." Their mediation is intervention rather than facilitation — interrogating rather than adopting tools, asking what is gained and whose labor disappears, and treating context as an epistemic principle rather than a design preference. The author's analytical contribution is to separate digital inequality from **algorithmic coloniality** and to insist, following Adams, that calls to decolonize AI stay material rather than metaphorical.
- **Situated and cultural-historical ethics.** Critical approaches also argue that AI ethics in education must be *situated* — grounded in cultural-historical and ecological context rather than abstract principles.(Situated AI ethics: a cultural-historical and ecological framework for education)
- **Sustainability as a value-based project.** AI's effect on educational sustainability is conditional and governance-mediated, not intrinsic: a value-critical analysis holds that AI supports sustainable education only when adoption is subordinated to explicit educational values and undermines it when technologization and commodification erode them (Alsuhami & Atallah (2026)).
- **Efficiency-first alignment discourse as an erasure of context.** McInnes et al. (2026) apply Fairclough's three-dimensional model to 14 pieces of gray literature (November 2022 – April 2025) advising higher-education practitioners to use generative AI for constructive alignment, and find a techno-solutionist discourse in which the tool is anthropomorphized as "an educational expert and assistant" and academic staff are positioned as supplying "subject matter expertise" while the system performs the pedagogical work. The analysis names the erasure of situated, disciplinary and critical context as one of three failure modes — alongside performativity (alignment that only looks aligned) and shallow alignment that conflates the constructive dimension with the aligned one — evidence that even advice about course design, ostensibly a neutral technical matter, carries the depoliticising logic critical pedagogues critique elsewhere.
- **Design remedies are not enough on their own.** Human-centered design approaches such as value-sensitive design are insufficient: they leave the systemic drivers — workforce-productivity framings and economic incentives — untouched, and Learner Agency may be zero-sum, so capability handed to the tool is capability the learner does not retain (Prieto & Dimitriadis (2026)).
- **Human rights education as the test case for AI governance as formation.** Kasa-Mälksoo (2026) works through the UN's *about, through, for* framework in a law program and locates the difficulty not in the technology but in the pedagogy: students submitted polished written work and polished session designs without the engagement those artifacts are supposed to evidence, and the most critical thinking appeared in end-of-course writing rather than in class dialogue. Her conclusion shifts the educator's role rather than shrinking it — AI governance becomes a professional responsibility students are trained to contest, and the tool is directed rather than banned.

Assessment as a site of critique

Critical pedagogy enters assessment through the question of whose interests a redesign serves. Laidlaw (2026) builds that case by joining the Theory of Practice Architectures to critical pedagogy, so that an assessment reform has to move three things at once: the cultural-discursive language that makes some practices thinkable, the material-economic arrangements of tools and resources, and the social-political distribution of power. The framework's warning is specific. When resources flow through existing power structures without explicit equity attention, a well-intentioned redesign amplifies the inequities it was meant to address, which makes the resource-power intersection both the largest leverage point and the largest risk. Her four-phase matrix runs critical analysis, intervention design, equity-focused implementation and evaluation, and she treats incremental change and productive tension as legitimate outcomes rather than as failure to transform quickly.

The role of the educator

Under critical pedagogy, educators are not neutral transmitters of AI skills but critical interlocutors and facilitators who help learners interrogate the politics of AI. This connects to the knowledge base's Teaching and AI Literacy concepts, and to the broader concern with Equity and Reducing AI Misuse. The educator's task is to cultivate spaces where communities can collectively question, appropriate, or refuse AI — keeping education a site of imagination and social transformation. Burriss et al. (2026) add a practical condition to that role: open-ended critical AI literacy work does not require educators to arrive as AI experts, only to be willing to explore alongside students — a joint student–teacher investigation of one specific system, electronic "hall passes" (not all of which are AI), surfaced and worked through Misconceptions about AI while deepening technical knowledge. Miles, Haber-Curran and Arar (2026) give that role a constructionist, ethics-of-care shape: they treat prompt literacy as a rhetorical, ethical and reflective process rather than a technical optimization skill, and the framework's closing phase has students co-design a Personal AI Use Policy with their instructor, so the norms governing classroom AI use are authored by the people they govern rather than issued to them.

Common Misconceptions

"Using AI critically means using it less." Critical engagement is a mode of use, not a quantity of use. Across **42 classroom episodes** in a Romanian lower-secondary study, **15 (35.71%) were AI-dependent** and **16 (38.10%) AI-enhanced**, leaving only **11 (26.19%) AI-critical** — so the enhanced and the critical episodes both involve the tool, and the distinction is whether students interrogated it. The scarcity of the critical mode is a teaching problem, not a usage problem.

"AI literacy is a neutral skillset." Critical pedagogy treats it as a practice of resistance and social transformation, which makes the framing itself contestable. A literacy curriculum that teaches prompting technique and omits whose interests the system serves has taught fluency in a tool while adopting its politics uncritically.

"Critical pedagogy is a critique offered from outside practice." It is a stance toward the educator's role: asking who benefits, whose knowledge is privileged, and how schooling reproduces or resists power. Applied to AI adoption, that means interrogating the corporate and capitalist logics shaping procurement —

questions an instructor can ask about their own institution's choices, not only about the technology in the abstract.

"Centring marginalised epistemologies is a curriculum-content addition." It changes whose knowledge counts as knowledge, which is a question about the structure of the course rather than an added reading. Content additions leave the frame intact; critical pedagogy's claim is on the frame.

Implications for Practice

For instructors

- Count your critical episodes. If the 26.19% figure describes your practice, the target is a shift in the mode of use rather than less use.
- Make procurement a teachable object: ask with students whose interests a chosen tool serves, and who bears the cost of its errors.
- Treat AI literacy as interrogation of the system, not only competence with it.
- Make the justification the assessable artifact. In a course unit that used Benali and Díaz García's (2026) drafting, revision and reflection workflow with 96 final-year students in 24 groups, AI was confined to two sections of a research proposal and every accepted or rejected AI suggestion had to be justified in writing. Students' reflective reports describe that verification work, not the drafting, as what produced the critical stance, which is why the record of judgment is the thing to grade.

For developers and administrators

- Expect critical pedagogy to interrogate your incentive structure rather than your feature list, and answer the question about whose knowledge the default output encodes.

For researchers

- Report the distribution of engagement modes in classrooms, not only average use, since the mean conceals whether any critical practice exists.

Pedagogical Partnerships

> **Pedagogical partnerships** (also known as **students as partners** or **SaP**) — a relationship-centered approach to teaching and learning in which students and educators work together as collaborators to co-create curriculum, teaching activities, Assessment, open educational resources, and educational policies, rather than treating students as passive recipients of faculty-designed instruction. Rooted in values of **respect, reciprocity, and responsibility** (Cook-Sather et al., 2014), pedagogical partnership repositions students as co-creators of knowledge and educational innovation and challenges traditional top-down power dynamics in education. In the AI era, partnership has become a key counter-narrative to deficit views of students as AI cheaters or victims — positioning students as partners in co-designing AI policy, tools, and practice.

Questions to Consider

- When you design a course, assignment, or policy, who typically makes the decisions — and whose perspective is left out? What would change if the people most affected by those decisions were genuine collaborators rather than recipients?
- A common assumption is that students lack the expertise to contribute to teaching design. Yet partnership research argues students are experts in their own experience as learners. Where is the line between a student's legitimate experiential expertise and the faculty member's disciplinary expertise?
- The word "partnership" can paper over real power differences — a student asked to "co-design" a course still depends on the instructor for grades and references. What conditions make a partnership genuine rather than performative?
- In the age of generative AI, students are often framed as either cheaters or victims. How might reframing them as partners in designing AI use and policy change both the tools built and the conversations educators have with students?
- Partnership can extend to whole classes, small groups, or individuals. Which form is most equitable, and what practical and resource constraints limit broader participation?
- What does trust have to do with pedagogical partnership — and how might surveillance- or deficit-oriented responses to AI fracture the relationships partnership depends on?

Introduction

Pedagogical partnerships, also called **students as partners (SaP)**, describe a spectrum of practices in which students collaborate with academic staff to shape teaching, learning, assessment, curriculum, and the broader student experience. The approach draws on the foundational guide by Cook-Sather, Bovill, and Felten (2014) and the higher-education framework of Healey, Flint, and Harrington (2014), which describe partnership as grounded in three core values: **respect, reciprocity, and responsibility**. Partnership is not about making students pedagogical experts, nor about faculty relinquishing disciplinary authority; rather, it recognizes the

complementary roles each partner brings — faculty as disciplinary experts and intellectual guides, students as experts in their own experience as learners with diverse talents and interests.

Pedagogical partnership challenges the entrenched assumption that students cannot be trusted to collaborate on teaching and learning, and it actively disrupts traditional faculty-centered hierarchies. It overlaps conceptually with Collaborative Learning, learner agency, and Student Engagement, but is distinct in centering students in the *design* of education itself — curriculum, assessment, teaching activities, open educational resources, and policy — rather than merely as active participants within a pre-designed course.

In the generative AI era, pedagogical partnership has taken on new urgency. As AI amplifies deficit narratives that frame students as either cheaters or victims (see AI Misuse and Learning Harm and Framing AI Use for Students), partnership offers a counter-narrative: rather than policing students or assuming misuse, educators and institutions can engage students as co-designers of AI policy, tools, and practice. This is reflected across the knowledge base's research — from students co-designing course AI policies to co-creating custom AI tools and co-constructing assessment criteria.

Forms and scope of partnership

Partnership can take many forms and operate at multiple scales, each with distinct affordances and constraints:

- **Whole-class partnership (co-creation in the classroom):** All students in a course collaborate with faculty on course structure, content, goals, and policies. Whole-class approaches may be the most equitable form of partnership because they allow broad participation and benefit, though they require substantial "high-touch" personnel resources to support increased student decision-making (Bovill, 2020).
- **Individual or small-group partnership:** A small number of student partners work with staff on a specific project — for example, co-designing Assessment criteria, evaluating AI tools, or developing curriculum. These are well-suited to dialogic, in-depth collaboration.
- **Project- or program-based partnership:** Students partner on a bounded initiative, such as co-designing a course AI policy, building a custom AI tool, or developing an algorithmic-literacy program.
- **Partnership in Curriculum Design and Learning Design:** Students contribute to shaping what and how learning happens, from individual activities to entire programs.

Across these forms, partnership is a *process and a relationship*, not just an activity. The outcomes are often co-created and not fully defined in advance, which requires staff to let go of control and accept the risks of the unknown — values that run counter to the hidden rules of much of higher education.

Pedagogical partnership and AI in education

The intersection of pedagogical partnership and AI is one of the fastest-growing strands of the knowledge base. Key themes:

- **Students as co-designers of AI policy.** Rather than institutions imposing AI rules on students, partnership positions students as co-creators of course- and institution-level AI policy. For

example, a guided-inquiry activity in which students co-designed a Generative AI course policy surfaced student priorities around training, standardized disclosure, institutional support, and involvement in decision-making (A Guided Inquiry Approach to Students Co-Designing Generative AI Course Policies).

- **Students as co-creators of AI tools.** In students-as-partners frameworks, students have co-designed and refined custom AI chatbots aligned with pedagogical goals — an approach that extends the SaP paradigm to include AI tools themselves and positions student voice as central to responsible AI innovation (Co-creating custom GPTs: An autoethnographic study of undergraduate students as partners in generative AI innovation).
- **Co-creation at scale, measured cautiously.** In a 710-student software design course, students built an AI tutor for a peer instead of using one. Design freedom was the top positive theme (22.3%) and unclear instructions the top complaint (23.7%), but perceived learning correlated with quiz scores only at r = 0.161 to 0.315 and the design had no control group (Zangari et al. (2026)). Building the tool is a plausible pedagogy and, on this evidence, an unproven one, which is why the case for it rests on the design activity rather than on outcome gains.
- **Whole-class co-design, evaluated by Self-Assessment.** A first-year information-studies program had students and faculty co-design course goals and policies in the first week and revisit them through the term, with students grading themselves and their groups against personal goals, team goals and a shared rubric rather than final products (Maybee, LeGrand & Fundator (2025)).
- **Co-creation in assessment and AI.** Student-staff partnerships have co-evaluated AI-generated output in coursework assessments and co-designed evaluation criteria, improving understanding of AI's benefits and limits and supporting Self-Regulated Learning (Assessment design through co-creation: Student-staff partnership in evaluating the impact of artificial intelligence).
- **Partnership to preserve pedagogical trust.** In the face of AI-driven uncertainty and "AI shame," partnership practices that nurture *pedagogical trust* — a confident, reciprocal learning relationship open to uncertainty and co-navigated through dialogue — offer a way to sustain the relational core of education (Five guiding principles for navigating artificial intelligence in students as partners practice to preserve pedagogical trust).
- **Youth as co-designers of AI systems.** Participatory design approaches engage historically minoritized students as partners in designing the AI systems that will affect their classrooms, surfacing students' values and ethical commitments (Co-designing AI with youth partners: Enabling ideal classroom relationships through a novel AI relational privacy ethical framework).
- **Students' lived realities as a design input.** Frameworks like entangled pedagogy illuminate the complex, "messy" realities students navigate with AI, arguing that policy and guidance should be co-designed with students in light of their lived experiences rather than imposed from above (Illuminating complex student realities of artificial intelligence through an entangled pedagogy framework).

These strands share a core claim: that the people who will live with AI in education — students — must be meaningfully engaged in shaping it, or the resulting tools, policies, and practices risk being untrustworthy, inequitable, or ineffective.

Relationships to related concepts

Pedagogical partnership is related to but distinct from several neighboring concepts:

- **Learner agency and Self-Directed Learning:** Partnership supports learner agency by giving students a voice in what and how they learn, and it overlaps with self-directed learning. However, partnership is fundamentally *relational* — agency and direction emerge through the instructor–student relationship rather than in isolation. Some frameworks conceptualize this as "shared agency" that exists in the relationship between student and instructor, not within either party alone.
- Anastasia (2026) names the eight conditions such a partnership requires — instructor presence, trust, psychological safety, dialogue, voice and choice, meaningful feedback, reflection, and shared responsibility — and argues that choice alone does not create autonomy: students may be handed options while lacking the information, confidence, or psychological safety to exercise them (Anastasia (2026)).
- **Collaborative Learning:** Both involve working together, but collaborative learning typically refers to students learning *with each other* within a designed activity, whereas pedagogical partnership centers students and staff collaborating on the *design* of education itself.
- **Student Engagement:** Partnership is a deep form of engagement, but engagement describes a student's involvement in learning while partnership describes a changed power relationship in which students share responsibility for shaping that learning.
- **Teaching:** Partnership redefines the teacher's role from sole authority and gatekeeper of knowledge to co-designer and intellectual guide, without diminishing faculty expertise.
- **Assessment and Authentic Assessment:** Co-designing assessment — from evaluation criteria to rubrics to whole assessment formats — is a central arena of partnership, and AI has amplified both the need for and the difficulty of genuine co-design in assessment.
- **Educational AI Policy and AI Governance:** Partnership extends into policy and governance, positioning students as co-creators of AI policy rather than passive subjects of it.
- **Equity and Inclusive Learning:** Partnership is argued to be a more equitable form of educational participation, centering voices — especially those of historically minoritized or marginalized students — that are often excluded from educational decision-making.

Key research themes

- Whether and how partnership improves learning outcomes, Student Engagement, Motivation, and a sense of belonging.
- The relational conditions — trust, psychological safety, dialogue, shared responsibility — required to bring partnerships about and sustain them.
- How AI both enables and complicates partnership: as students co-design AI tools and policies, and as deficit narratives around AI threaten the trust partnership depends on.
- Equity in partnership: which students get to participate, whose voices are centered, and how whole-class vs. selective forms distribute benefit.

- The resource and institutional constraints on partnership, including the time-intensive nature of genuine co-design.
- How partnership relates to decolonizing, critical, and critical pedagogies that challenge traditional hierarchies and center multiple ways of knowing.
- **Mentoring can run in both directions.** In a 20-fellow, 15-intern program across 14 Columbia departments, interns taught faculty AI tools while faculty taught disciplinary standards, most pairs settling into a Translator model (Zheng (2026)).

Practical implications

For educators and institutions seeking to adopt pedagogical partnership, the knowledge base's research suggests:

1. **Start small and iterate.** Begin with a bounded project — a pilot with a limited number of participants — and honor participant effort with recognition (employment, credit, certificates, publication).
2. **Build on existing infrastructure.** Faculty development programs, student employment relationships, and cross-campus partnerships provide foundations for adapting partnership practice.
3. **Lead with relationship and trust.** Partnership works when trust, psychological safety, dialogue, and shared responsibility are deliberately cultivated — not assumed.
4. **In the AI era, invite students in rather than policing them.** Co-designing AI policy, tools, and assessment with students is both more equitable and more effective than deficit-based responses.
5. **Consider equity of participation.** Whole-class partnership offers the broadest participation; selective programs must attend to which students are invited and included.

Common Misconceptions

- **"Partnership means elevating student voice."** A pedagogical partnership is a **bounded, negotiated relation** with defined roles and reciprocal obligation, not consultation. Voice without a role, a remit and a share of the decision changes nothing structural.
- **"Partnership is a stance one can adopt."** It requires institutional conditions — time, recognition for the student partner, and a change the partners can genuinely affect. Declared partnership without those conditions reproduces the hierarchy it claims to interrupt.
- **"Power-sharing cannot be faculty development."** The claim of the literature is that partnership is development *because* it changes the educator's understanding through the relation. Framing it as student benefit only discards the mechanism.

Storytelling in Education

> **Storytelling in education** — the use of narrative as a pedagogical tool to engage learners, convey meaning, and support knowledge construction, creativity, and emotional connection. Storytelling is a natural and motivating way for learners to make sense of the world, and it is increasingly combined with technology — including AI and social robots — to create interactive, adaptive narrative experiences. Digital and robot-mediated storytelling can add interactivity, personalization, and embodiment that conventional (paper-based or slide-based) storytelling lacks.

Questions to Consider

- Think of a lesson or concept you remember vividly because it came as a story. What did the narrative add that a plain explanation didn't, and can that power survive being outsourced to an AI or a robot?
- The page describes robot- and LLM-mediated storytelling that responds to the learner and supports co-creation. What do you imagine is gained — and potentially lost — when a story is co-built with a machine instead of told by a person?
- If storytelling builds engagement, creativity, and emotional connection, where might its use in education be more than entertainment — and where might it risk substituting feeling for understanding?
- A robot storyteller increased behavioral and cognitive engagement over paper and PowerPoint in the research cited. Do you trust that engagement translates into learning, or could the novelty of the robot be doing the work?
- How could you tell whether a learner is genuinely making meaning from an AI-co-created story versus just enjoying the interactive experience?

Introduction

Storytelling is grounded in Motivation, Student Engagement, and Constructivism theories of learning. It supports Language Learning, Creativity, Social-Emotional Learning, and comprehension. In the AI era, LLM-powered and robot-mediated storytelling enables co-creation, where learners and AI agents build stories together, and interactive narrative that responds to the learner.

How storytelling appears in the knowledge base's research

- **Robot-mediated storytelling:** MotiBo uses a human-like interactive digital storytelling robot, finding significant gains in behavioral and cognitive engagement over paper and PowerPoint methods; RoboBuddy lets teachers create LLM-powered scenario-based storytelling activities from curriculum content.
- **Engagement gains have a size, and motivation did not follow.** MotiBo finished 27.06% and 30.00% ahead of paper and PowerPoint on behavioral and cognitive engagement (both $p < .05$),

while intrinsic motivation rose 20.21% without reaching significance ($p = .07$). Engagement moved, motivation did not clear its threshold, and the five-day quasi-experiment measured no learning outcome (Fung & Lui, 2026).

- **Co-creative narrative HRI:** The iCub narrative study explores human-robot co-creation of stories, integrating generative models for contextually appropriate interaction.
- **Narrative and creativity:** Storytelling supports Creativity and language development, and is used to enhance motivation and engagement in K-12 settings.
- **Digital storytelling as a counterweight to AI:** As generative AI ascends, digital storytelling is reframed as a vehicle for the emotional, cultural, and narrative capacities that AI lacks. In a project-based learning model for art and design education, students translated local cultural heritage into Multimodal AI narratives across 92 digital storytelling works, demonstrating how storytelling sustains human creativity in the AI era.
- **Generated narrative is easy to produce and hard to keep coherent.** With 22 STEM students, AI-generated interactive fiction rated well on narrative clarity ($M = 4.11$) and length ($M = 4.14$), but engagement sat at the neutral midpoint ($M = 3.08$) and story-content coherence was weakest ($M = 2.92$) (AI-Generated Interactive Fiction for Educational Use: A Pilot Study of Perceived Comprehensibility, Coherence, and Engagement). Co-creation inherits that weakness at the layer a story is supposed to do its work.

Storytelling connects to Student Engagement, Motivation, Creativity, Robots in Education, Language Learning, Social-Emotional Learning, and Robots in Education.

Common Misconceptions

“A co-built story is a told story.” What is gained is fluency and volume; what is at risk is the teller’s authorship. A story is a structuring of experience by someone who chose the sequence and the emphasis, so a machine that supplies the structure has supplied the part that carries the meaning.

“Storytelling is a soft addition to content.” Narrative is a memory and sense-making device, and the learner who narrates is doing the organizing work. Handing over the narration hands over the learning.

“AI generation makes storytelling available to students who could not write.” It makes *producing a written artifact* available, which is a different benefit. Oral narration, drawing and dictation are the established routes to the same goal, and they preserve the authorship that generation removes.

“The educational value of a story is in the polished result.” It is in the construction — the selection and ordering that a teller performs. A polished story the student did not structure has demonstrated the model’s competence rather than the learner’s.

Online Teaching and Learning

> **Online teaching and learning** — the pedagogy and practice of teaching and learning that happens through digital, network-mediated environments rather than in a shared physical classroom. It spans fully online courses, Massive Open Online Courses (MOOC), blended and hybrid formats, and distance education. For the knowledge base, the central question is how Generative AI reshapes the opportunities, challenges, and recommended practices of teaching at a distance — from scalable personalization to new Academic Integrity and Cognitive Offloading risks.

Questions to Consider

- You've likely taken an online course or taught one. What did you lose and what did you gain when the physical classroom was removed—and how did that reshape what instructors could rely on?
- The page argues online teaching is a distinct pedagogy, not just a delivery mechanism. In what concrete ways does the online medium change which teaching strategies are even possible or effective?
- An RCT found unguarded AI assistance raised practice performance but lowered unassisted exam scores, while a 'hint-not-answer' tutor removed the harm. Before reading further, can you explain why giving students the answer might inflate immediate performance yet erode durable learning?
- Online assessment can't always tell assisted from independent work. If detection tools are a 'partial, contested response,' what alternative assessment designs might reveal genuine understanding instead?
- How does the perceived availability of an effortless AI shortcut reshape student motivation in a self-paced, screen-based course? What might you design to counter it?
- An autonomous agent can now log into a learning management system, read the material, answer the quiz and post to the discussion. If producing the artifact no longer demonstrates learning, what would you need to see instead?
- AI can now generate a MOOC-equivalent course in minutes at a fraction of the cost. What are the pedagogical trade-offs of 'N agents for one student' versus 'one video for N students'?

Introduction

Online teaching and learning is a distinct pedagogical context, not merely a delivery mechanism. It removes the physical co-presence that scaffolds attention, Motivation, and informal interaction, and it substitutes structured digital interaction — discussion forums, asynchronous materials, video, tutoring agents — for face-to-face contact. This changes what instructors can rely on, what students can access, and how learning is designed and assessed. As an umbrella concept in the Pedagogies and Teaching Strategies landscape, it sits alongside Active Learning, Collaborative Learning, and Self-Regulated Learning but is distinguished by the medium: the constraints and affordances of the online environment shape which strategies are viable.

The rise of generative AI lands directly in this context. Online learners already work through screens and software, so AI tools are natural neighbors; at the same time, online assessment is harder to invigilate, making misuse easier and the stakes higher. The evidence in this knowledge base shows that AI can be a powerful ally for online teaching and learning — and, configured poorly, a significant source of learning harm.

Lock, Arteaga & Johnson (2025)'s critical literature review (63 citations across 32 countries) organizes this landscape into four interconnected themes that recur throughout the page below: the types and purposes of AI integration, pedagogical approaches (AI literacy, self-regulated learning), benefits, and challenges. Their central caution — that these themes *overlap* and that online AI integration is a sociotechnical undertaking anchored in pedagogy and human relationships rather than technology adoption alone — aligns with the page's framing of online teaching as a distinct pedagogy. Notably, they report that students using ChatGPT *alongside* teacher tutoring perceived greater Learning Gains than those using it alone, reinforcing the hybrid human–AI collaboration emphasis threaded through this page.

The development that moved this from a design question to an urgent one is that generative AI no longer only writes text a student could have written. Autonomous agents now log into a learning management system, read the course materials, answer the quizzes, read classmates' posts, and submit the work. Three demonstrations on a live undergraduate psychology course show what that means in practice: two quiz completions, one in roughly **12 minutes** and one in **under 5 minutes**, both scoring **10/10**, and a discussion post in which the agent mined its peers' posts and then fabricated a credible first-person life history to answer them — against a public record of at least **15 documented agent runs** across Canvas, Moodle and Brightspace using **seven agent tools**. Hadjisolomou and El-Haddad (2026) argue this is an Assessment Validity problem before it is an integrity one: what agent completion removes is the assumption that the submitted work was produced by the person whose learning is being assessed. The design question for online teaching therefore shifts from how to detect misuse to what evidence of learning an online course can still produce, which is the thread running through the sections below.

Formats and settings

Online teaching and learning takes several related forms that share the medium but differ in reach and structure:

- **Blended and hybrid learning.** Models that combine in-person and online components, intentionally integrating digital activities, materials, and interactions with face-to-face teaching. Blended formats ask instructors to decide what is best done synchronously vs. asynchronously and online vs. in person — decisions that Learning Design principles organize and that AI both supports and complicates. In the blended context, AI tools offer opportunities for personalization and always-on support while raising integrity and offloading risks that span both the online and in-person portions. Mejia-Domenzain et al. (2026) illustrate this in two blended settings — flipped university classrooms and reflective writing in vocational education — where a learning analytics dashboard (DashED) communicated ML-derived Self-Regulated Learning profiles to teachers. Adoption concerns diverged by context: flipped-classroom (university) teachers worried most about data anonymization and student opt-out, whereas reflective-writing (vocational) teachers feared misuse of the tool by fellow educators and stressed the need to contextualize data. In use,

flipped-classroom teachers followed a sequential exploration and favored course-level adaptation and showing dashboards in class, while vocational teachers revisited summary pages and used the tool mainly for individual coaching sessions — evidence that blended analytics design must be context-aware.

- **Synchronous versus asynchronous design.** The distinction matters more than the delivery medium, because the two formats make opposite demands on the learner. Synchronous sessions carry attention, pacing and accountability inside the session itself; asynchronous courses have to design them in, since the learner alone decides when to work and receives no ambient accountability from a room. The research base often blurs this: the knowledge base's review of AI and engagement in online learning (24 studies) treats engagement alone and explicitly conflates synchronous with asynchronous contexts, so its conclusions should not be read as asynchronous-specific. What is asynchronous-specific is the evidence on how self-paced learners lose focus and pace — self-regulated behaviors such as goal setting, environment structuring and time management coincide most with low digital distraction (Shi et al. 2026, 530 students), while metacognitive knowledge and Well-Being decline across a term in step with clustered assessment deadlines (Song et al. 2026, 75 students). The practical counterpart is the FAQ on designing and facilitating asynchronous courses when AI can do the work.
- **Distance education.** Programs designed for learners who study remotely, often at scale and across regions (e.g., the Open University's 200K+ learners). Distance learning is where 24/7, context-embedded AI support and the impossibility of in-person invigilation are most salient. Comparative evidence from South African teacher preparation shows the medium itself is associated with preparedness. Mnguni et al. (2026) reported a gap in self-reported TPACK for AI-integrated science teaching of 64.0% against 47.4% between final-year trainees on campus-based and distance programs, with Pedagogical Knowledge weakest at both institutions. The pattern warns that distance programs cannot assume that the same AI training produces the same readiness, and that the design of the training, not its presence, is what differs.

Opportunities and benefits of AI for online teaching and learning

- **Scalable personalization.** Traditional MOOCs excel at reach but struggle to adapt — "one video for N students." Large Language Models (LLMs)-driven agent systems (MAIC) invert this to "N agents for 1 student," using specialized Teacher, Assistant, Classmate, and Analyzer agents to deliver adaptive instruction, personalized feedback, and dynamic learning paths at MOOC scale. Systems like LearnMate² address the "personalization gap" in open online learning with personalized study plans, real-time contextual assistance, and adaptive activities. Personalized video is a concrete route to this goal: Tomlinson et al. (2026) found students in a large online course preferred AI-generated personalized videos over non-personalized human-recorded ones — a preference whose personalization effect outweighed the value placed on a human presenter — suggesting scalable, Generative AI-produced personalized media can close the "one video for N students" gap in online instruction.
- **Always-on, context-embedded support.** In distance and adult learning contexts where learners study at work or at home, 24/7 support embedded in the course is a major benefit. The Open University's AIDA assistant found purpose-built, in-environment GenAI support increased

engagement (doubled usage time in an exploratory trial), with 96% of students wanting it in their formal studies.

- **Conversational, dialogic tutoring at scale.** Conversational AI tutors built on proven Intelligent Tutoring technology (keep/change/center/study framework) promise high-quality, dialogue-based tutoring — engaging students' thoughts, questions, and Misconceptions about AI — that is far more scalable than human tutoring.
- **Facilitation and analytics.** AI can support online discussions and Learning Analytics, forecasting engagement, and helping instructors allocate attention. Hao & Cukurova (2026) add that LLM-generated discussion summaries can act as navigational scaffolds in large asynchronous forums — broadening students' peer exposure and the network conditions for bridging social capital without burdening students or instructors with the summarizing workload.
- **Early-warning analytics for at-risk online learners.** Zhang, Jeffries & Koprinska (2025) show that interpretable machine learning on content-interaction logs predicts module-level progress and flags dropout ("No submission") outcomes in large-scale online programming courses up to 7–8 days before module deadlines, giving online instructors a concrete window to intervene with disengaged students rather than discovering failure only after the fact.
- **Affordability and speed.** AI can generate course materials at a fraction of traditional cost — MAIC reduced MOOC course production from ~$25K/60 hours to under $2/30 minutes.

Challenges of online teaching in the AI era

The online medium and generative AI combine to intensify a specific cluster of challenges that instructors must confront head-on. Where face-to-face teaching can rely on presence, immediate accountability, and invigilation, online teaching must design explicitly for them.

Academic integrity and cheating

Online courses already present invigilation challenges — in-person proctoring is often unfeasible for distributed, asynchronous learners. Generative AI compounds this by making AI-generated work indistinguishable from student work and by enabling contract-cheating style shortcuts at scale. The knowledge base's evidence on Academic Integrity and AI Misuse and Learning Harm shows that misuse is driven less by AI errors than by students copying answers instead of learning. Because online assessment frequently cannot distinguish assisted from independent work, misuse can inflate immediate grades while eroding durable knowledge — a perceived-vs-actual gap that is especially dangerous at a distance where instructors have less visibility into student process. Detection tools are a partial, contested response (AI plagiarism detection, Remote Proctoring), and the knowledge base's stance favors authentic, process-revealing assessment over detection arms races.

AI misuse and cognitive offloading

The most serious risk is that online learners outsource the very cognitive work that builds understanding. The performance–learning gap shows generative AI easily boosts immediate performance while bypassing the deep processing required for durable learning. Field evidence is direct:

- A causal RCT (~1,000 high-school math students) found unguarded AI assistance raised practice performance **+48%** but reduced unassisted, closed-book exam scores **−17%** — the students who never had AI access outperformed those who did. A guardrailed hint-not-answer tutor eliminated the harm.
- Population-scale behavioral data (3.2M ALEKS interactions) found study time on AI-susceptible problems fell **−26.9%** after ChatGPT's release, with a **−25% decline in odds of correct proctored retention items** — an effect that vanished under proctoring, pinning it on off-platform AI use.

Online learning is particularly vulnerable: the medium already distances learners from immediate accountability, and self-paced, screen-based work invites the "ask for the answer" shortcut that Cognitive Offloading research identifies as the core harm mechanism. The response is not to ban AI but to apply Guardrails — hint-not-answer scaffolding, knowledge grounding, and human oversight — so that AI augments rather than replaces learner cognitive work.

Other challenges

- **Over-eager AI facilitation.** LLM facilitators are excessively eager to intervene in online discussions, which can irritate participants and derail good conversation; human caution is the better model (Tsirmpas et al.).
- **Motivation erosion.** The perceived availability of an effortless AI shortcut reduces autonomous Motivation and persistence, compounding learning harm.
- **Equity and the digital divide.** Access to reliable devices, connectivity, and high-quality AI varies; online learning with AI can widen rather than narrow Equity gaps (Digital Divide).
- **Data privacy and trust.** Online platforms collect rich learner data; AI systems raise transparency and privacy concerns (Privacy), especially for adults balancing work and study.
- **Organizational readiness.** The demise of KhanMigo — learners not actually engaging with the chatbot, with limited evidence of gains — cautions that technical capability must be matched with AI Governance and organizational readiness.

Assessment validity when a submission can be produced without the learner

If invigilation is unfeasible and an agent can complete the work, the response the knowledge base favors is to change what counts as evidence rather than to police harder. Four design responses recur across the recent literature.

Pair the vulnerable task with a twin. Roe, Perkins and Giray (2026) keep the pedagogically valuable but AI-vulnerable assessment — the take-home essay or case analysis — and add a second, less vulnerable task that assesses the *same* learning outcomes, scheduled closely enough for cross-verification and marked

interdependently. Their mapping runs across Messick's six strands of validity evidence, and the design process is three steps: identify the vulnerabilities, align outcomes and choose the twin, then develop marking that connects the two. A short case variation, an explanation of one key decision, or a brief oral defense can serve as the twin.

Target ownership rather than authorship. Ebrahimzadeh, Shibani and Buckingham Shum argue that blended human–AI authorship undermines several forms of validity evidence, and propose **coauthorship integrity** as validity evidence in its own right: violated when a student submits AI-generated content they do not understand. To check understanding at scale they report an **AI Viva**, a conversational agent that runs a hybrid viva voce with comprehension questions of controllable type and complexity, validated by expert educators and assessment specialists. For online courses this is a genuinely scalable form of verification, and it produces evidence about comprehension rather than about who was in the room.

Move the oral exam online. Pentland, Lowenthal and Krier (2026) deliver prompts just in time and have students record brief, time-limited webcam responses they cannot revisit, graded against embedded rubrics with transcripts generated automatically. Across two studies — an intermediate accounting pilot and a data analytics course — students scored higher on these assessments than on in-person multiple-choice exams (significant in the second study, a positive trend in the first), with moderate cross-format correlations supporting convergent validity; students reported preparing differently and using more active study strategies. The format addresses the async problem directly: the thinking is performed live at a time of the student's choosing, at administrative cost that does not scale with cohort size.

Sequence the work so the reasoning is committed first. Brcic and Frljic (2026) frame the design question as **placement** rather than permission, and the causal evidence they assemble shows the outcome flipping on placement alone — the same unguarded helper that left high-school students about **17% worse** on an unaided exam did no harm once rebuilt to withhold answers, while a well-engineered tutor roughly **doubled** learning. Their diagnostic is the one to keep: *if letting AI in makes the task feel effortless, it is in the wrong place*. Operationally that yields a sequence an online course can write into the assignment — think, commit, use AI, critique, revise, explain — where the commitment step is what makes the rest assessable, because an artifact produced from scratch has no revision history to interrogate. Underneath sits a state this knowledge base names metacognitively discordant completion: correct, complete work submitted by a student who knows the understanding never arrived, which in an asynchronous course is indistinguishable from success unless the design asks for something more.

Whatever combination an instructor chooses, one constraint should shape it. Online study is frequently the only accessible option — students choose it because of employment, caregiving responsibilities, disabilities or geography — so verification has to be **small and proportionate**: a short recorded explanation, a personalized application, a response to an instructor-selected question, an annotated decision trail, a low-stakes individual check. Detection carries its own equity costs here, since tools that flag non-native writers disproportionately generate false positives (AI Detection, Digital Divide).

Recommended pedagogical strategies for online teaching and learning

- **Active and interactive learning.** Prefer strategies that keep students doing and thinking rather than passively receiving — Active Learning, interactive exercises, and Socratic dialogue. AI that

prompts reasoning (rather than supplying answers) preserves the productive struggle and Desirable Difficulties that build durable learning.

- **Scaffolded, guided support.** Use Scaffolding that fades as learners progress, and design Self-Regulated Learning supports so learners direct their own learning rather than depending on the tool.
- **Collaborative and discussion-based learning.** Structure online discussions and group work deliberately; use Collaborative Learning activities and, when AI participates, calibrate its facilitation and its role as a peer.
- **Role design is the intervention, not the tool.** In an online graduate course, assigning rotating moderator, analyst, and arguer roles to Learners and a generative AI partner raised group mind-map content scores from M = 3.65 to M = 4.59 on a 1-5 SOLO scale ($z = 3.771$, $p < 0.001$), while node and branch counts stayed statistically flat (Cheng et al. (2026)).
- **Authentic, process-revealing assessment.** Shift toward Authentic Assessment and assessments that capture process — drafts, oral defenses, self-explanation, reflective portfolios — which are more AI-resistant and reveal genuine understanding.
- **Personalized and adaptive paths.** Use AI-enabled personalization and adaptive activities to tailor pacing and difficulty, while keeping personalization deep (task sequencing, difficulty calibration) rather than merely surface-level (custom examples).
- **Social presence and community-building.** Deliberately cultivate social presence and community — the core of the Community of Inquiry framework — through companion AI, synchronous check-ins, and peer interaction, since online isolation is a key barrier to engagement and belonging. In the AI era this means curating the three presences (cognitive, social, teaching) even as machine-generated discourse complicates who is "present" (see Community of Inquiry).
- **Blended Design Thinking.** For hybrid formats, apply Learning Design principles to decide what is best done synchronously vs. asynchronously and online vs. in person, and how AI supports each.
- **Name the AI's role, and check the student still has one.** "Students may use AI" is too broad to design against. Roles carry different pedagogical consequences — a study of generative AI in marketing education distinguishes **tutor, teammate and tool** and shows each shaping teaching, social and cognitive presence differently (GenAI in Marketing Education) — so an online activity should be able to state its division of labor: the AI's job here is X, the student's job is Y. If Y contains little thinking, the activity needs redesigning rather than a stricter policy.
- **Sequence discussion as position, challenge, reconsideration.** The conventional asynchronous formula of posting once and replying twice is both superficial and agent-completable. A stronger structure asks students to commit to an interpretation, meet a counterexample or critique, then explain how their reasoning moved; what is graded is the movement between ideas rather than the post count. This also relocates teaching presence: replying mechanically to dozens of posts is the least valuable form of it, while synthesizing patterns across the discussion — the assumptions that keep recurring, the disagreements worth naming, the counterexample that unsettles a consensus — is the part no agent in this literature performs.

- **Human-in-the-loop governance.** Keep educators and instructors in the loop over AI tools, grounded in pedagogical content knowledge, so pedagogical intent — not the tool's default — drives design.

Implications for online instructors and instructional designers

- **Guardrail the AI, don't just supply it.** Use hint-not-answer Scaffolding that keeps learner cognitive work in the loop; the guardrailed-tutor RCT shows this eliminates the exam penalty that unguarded access causes. See the Guardrails concept for the full design layer (prompting, RAG (Retrieval-Augmented Generation) grounding, training, QA).
- **Design AI-resistant and proctored/unassisted assessments.** Because online grading often can't distinguish assisted from independent work, include closed-book, proctored, or process-revealing assessments to surface and discourage misuse (AI Misuse and Learning Harm).
- **Teach AI literacy explicitly.** Help students recognize reliance patterns and calibrate trust (AI Literacy); build self-regulation and Metacognition to counter offloading.
- **Embed AI in the learning environment, not as an external bolt-on.** Purpose-built, contextually-tuned assistants embedded in the course (like AIDA) outperform generic external chatbots and increase acceptance.
- **Calibrate AI facilitation toward human caution.** When using AI to moderate discussions, prefer settings that intervene sparingly (Tsirmpas et al.).
- **Design for adult life constraints.** For adult and distance learners, prioritize mobile access, offline capability, and asynchronous availability (AI-ALOE guidelines).
- **Compressed formats need redesign, not compression.** Six-week asynchronous graduate courses for working teachers are an institutional constraint requiring purposeful redesign rather than a fifteen-week course compressed, and AI dialogue carries instructional presence into the late hours an instructor cannot staff Packard et al. (2026).
- **Co-design with students and staff, and build governance.** Participatory development, senior sponsorship, cross-unit collaboration, and robust AI Governance are enabling factors for responsible GenAI adoption.
- **Assume an agent will attempt every unproctored activity, and design from that assumption.** The three-question test is quick and exposes weak activities: could an AI system complete this without the student understanding the material; what cognitive activity is supposed to produce the learning; what evidence will show the student performed it. When the first answer is yes and the other two are hard to answer, the problem is the learning design rather than the AI policy.
- **Keep verification proportionate to the risk.** Where competence must be certified, prefer a twin task, an asynchronous oral defense or a short comprehension check over blanket monitoring; keep the rest of the course flexible for the learners who depend on that flexibility.
- **Use analytics to support, not replace, teaching.** Leverage Learning Analytics to forecast engagement and target support, but keep human oversight central.

Common Misconceptions

“Online teaching is classroom teaching delivered through a screen.” It is a distinct pedagogical setting, and AI lands differently in it. Self-reported TPACK for AI-integrated science teaching was higher among final-year student teachers at a campus-based university (**64.0%**) than at a distance-education university (**47.4%**), with the weakest domain in both settings being pedagogical. The distance setting compounds an existing preparation gap rather than receiving the same support.

“Adding an AI assistant to a course increases engagement.” Engagement depends on the assistant being purpose-built and in-environment. The Open University’s AIDA assistant raised engagement — doubling usage time in an exploratory trial — and that design condition is the finding: the same capability bolted on as an external tool does not recruit the same behavior. A generic chatbot link in a course shell is not the intervention that was studied.

“AI raises performance, so it raises learning.” In online settings the divergence is the same as in classrooms: an RCT found unguarded AI assistance raised practice performance but *lowered* unassisted exam scores, while a “hint-not-answer” tutor removed the harm. Online courses rely more heavily on asynchronous assessment, so the gap between assisted and unassisted performance is where validity is won or lost.

“Assessment validity is a grading-policy question.” It is a design question created by the medium: when a submission can be produced without the learner being present, validity depends on whether the task produces evidence that the learner did the work. Redesigning the task addresses this; tightening the penalty for misconduct does not.

Connected FAQs

- How Should We Design and Facilitate Asynchronous Online Courses When AI Can Do the Work?

Video in Education

> **Video in education** — the use of video as a medium for teaching and learning, and how generative AI is reshaping it: AI-generated and AI-personalized instructional videos, AI avatars and presenters, adaptive video generation, video-based learning analytics and attention/engagement sensing, and AI support for lecture-video consumption. The knowledge base treats video as both an established online-learning medium and a rapidly evolving site of AI innovation, spanning online, hybrid, and in-person teaching.

Questions to Consider

- Educational video has long been a "one-size-fits-all" resource — identical content for every learner. Generative AI now makes per-learner video feasible, and research suggests students value that personalization highly. What does personalization add beyond relevance — and what might it cost?
- Students often say they still value a human instructor's presence and authenticity in video. Yet in head-to-head preference, personalized AI video can beat generic human-recorded lectures. What tradeoffs are learners actually making, and how durable are they?
- AI avatars cloned from instructors can generate video at scale — but they can also trigger "uncanny valley" discomfort and ethical objections (environmental impact, labor, academic integrity). When is an AI presenter acceptable, and when does it cross a line that no technical fix addresses?
- Much video research relies on students' preferences and self-report. How well do stated preferences predict actual learning outcomes — and when might a video that "feels good" teach less well than one that does not?
- Video analytics can detect attention, engagement, and dropout points. What are the pedagogical and Privacy implications of instrumenting video learning this closely?

Introduction

Video is a cornerstone of contemporary education — especially online and hybrid learning — prized for its flexibility, scalability, and consistency. Yet conventional instructional video is produced as a one-size-fits-all artifact, presenting identical content to every learner regardless of their interests, background, or prior knowledge. Generative AI is shifting video from a static broadcast medium to a dynamic, individually tailored one, and is also generating new questions about presence, Trust, Privacy, and measurement.

How the knowledge base's research clusters

- **AI-generated and personalized instructional video.** A central thread asks whether students accept AI-produced video and how it compares to human-recorded content. Student surveys in computing education probe perceptions and preferences for AI-generated instructional video. In a

large field deployment, Tomlinson et al. (2026) found that students preferred AI-generated *personalized* videos over non-personalized human-recorded lectures — a preference in which the personalization effect outweighed the value placed on a human presenter. Dual gatekeeping research shows how instructor oversight ("gatekeeping") across two stages of AI video production yields more pedagogically grounded output, connecting to human-in-the-loop design.

- **Adaptive and structured video generation.** CourseBlueprint offers a structured pipeline that generates adaptive pedagogical video grounded in course corpora, showing that explicit pedagogical structure — not just AI fluency — drives effective AI video. Bespoke applies the same logic at whole-lecture scale: from 31 graduate lectures it generated 209 videos for healthcare, finance, energy, and a generic audience, and 25 domain-matched experts rating 92 of them placed 87% at or above the midpoint written as "a standard MOOC lecture's quality" (mean 3.42 out of 5), at about $0.22 in API cost per minute — with voice, slide timing, and layout the recurring defects.
- **A learning loop beats a better render.** Ma et al. (2026) plan each video as a storyboard of objectives, prerequisite activation, worked examples and diagnostic probes, paired with a quiz avoiding the video's examples and a remediation for each wrong option; 96.9% of 32 instructors judged the loop more effective than a standalone video.
- **Video learning analytics and attention.** Instrumenting video reveals how learners engage. Engagement assessment in video learning and SAVVY visualize student attention during video-based learning, supporting learning analytics, self-regulation, and early-warning for disengagement. Segmentation work (e.g., temporal video segmentation) tailors video to individual differences.
- **A neural read-out of video encoding.** EEG reconstructions of viewed video frames were more semantically similar for correctly answered questions (M = 71.43) than incorrect ones (M = 62.30, $p < .001$), and systematic temporal misalignment — reconstructions resembling earlier frames — was quantifiable as a dispersion measure associated with performance (Su et al. (2026)).
- **Avatars and presence.** AI avatars — virtual presenters and pedagogical agents — raise questions about identity, social presence, and trust. Avatar identity and epistemic trust examines how a presenter's apparent identity shapes learners' trust, while AI avatars in training extend the pattern to professional practice.
- **In-video scaffolding comments — and what AI still gets wrong.** Wang, Du and Jin (2026) generate *i-Comments*, Scaffolding messages rendered inside the video frame and synchronized to the content, by computing frame-level entropy and inserting support only in low-information intervals. Benchmarked against 120 comments from experienced instructors, ChatGPT's 1,000 comments were denser, far less structurally varied (POS 3-gram diversity 5.5–6.2% vs. 25.1–38.5%), harder to read on every readability index, and less topically aligned (emotional-support BERTScore 0.317 vs. 0.574); 40 learners rated the human comments significantly higher on timing and helpfulness, although a newer model narrowed that gap. The argument is a design argument as much as an automation one: support embedded in the media avoids the attention and cognitive cost of pausing to query a separate chatbot (feedback quality, emotional support).

- **AI support for lecture-video consumption.** Beyond generation, AI helps learners and teachers work with existing video: bilingual LLM lecture companions support self-regulated learning with recorded lectures, and transcription pipelines convert lecture video into accessible text.
- **Region-level zoom is the layer narrated slides were missing.** A within-subjects study with 24 viewers found automatic zoom plus synchronized highlights cut NASA-TLX workload from 5.74 to 4.53 (d = 0.84) and raised immediate comprehension (d = 0.46), though the 24-hour advantage missed significance (p = .054) (Lian et al., 2026).

Personalization versus human presence

A recurring tension is whether the value of personalization can outweigh the value of a visible human instructor. Tomlinson et al. (2026) frame personalization and social presence as *partially substitutable signals of instructional care*: human delivery enhances affective experience and authenticity, while personalization enhances relevance — and students are willing to trade one for the other. Their large-course ranking data (88.4% preferred some personalized video; only 73.8% preferred human-recorded) suggest personalization is now often the more influential factor, pointing toward a complementary model where human instructors supply expertise and social connection while AI extends their reach with individually tailored media.

Design, ethics, and measurement

Producing effective AI video requires pedagogical structure and human oversight, and it raises distinct concerns: AI presenters may evoke discomfort or distrust (the "uncanny valley"); generative video risks factual inaccuracy that learners may not catch; scaling personalization requires collecting or inferring learner attributes, with attendant Privacy, bias, and AI Governance concerns; and a subset of learners object to AI-generated instruction on principled grounds (environmental impact, labor, automation, academic integrity). Measurement is likewise in flux — much evidence rests on stated preference and perceived value rather than objective learning outcomes, so preference data must be read alongside (often forthcoming) outcome data.

Common Misconceptions

"Students preferred the AI video, so it teaches better." Preference and learning are separate measures, and much of this literature rests on the first. In a large online course (493 respondents), students ranked AI-generated personalized videos above non-personalized human-recorded lectures (mean rank 2.26 versus 2.69) and 88.4% ranked some personalized video first — a clean preference result. The page's own caution applies: evidence here rests substantially on stated preference and perceived value rather than objective learning outcomes, so preference data has to be read alongside outcome data, not in place of it. A video that feels better tailored is not thereby teaching more.

"AI-generated scaffolding comments can substitute for an instructor's." They differ in a way that matters for instruction. Benchmarked against 120 comments from experienced instructors, ChatGPT's 1,000 comments were *denser* but far less structurally varied (POS 3-gram diversity 5.5–6.2%), and 40 learners rated the human comments significantly higher on timing and helpfulness — though a newer model

narrowed that gap. Volume and density are not the same as the varied, paced commentary a good instructor produces, and the narrowing gap is a trend to track rather than a settled equivalence.

“Cloning an instructor into an avatar scales human presence.” It scales production and changes what is being delivered. AI avatars cloned from instructors can generate video at scale, but they also trigger uncanny-valley discomfort and raise ethical objections spanning environmental impact, labor and integrity. The presence being scaled is a simulation of the instructor, and the costs attach to the simulation.

“Generating many variants of one lecture is personalization.” Variant count is a production figure, not an instructional one. Bespoke generated 209 videos from 31 graduate lectures across healthcare, finance, energy and a generic audience, which demonstrates the pipeline’s capacity; whether any variant matched a given learner’s needs is a separate question that the generation count cannot answer.

Implications for Practice

For instructors

- Ask whether the evidence behind a personalized-video product is preference or achievement. The strongest numbers in this literature are ranks and ratings, and the two kinds of evidence point in different directions often enough to keep separate.
- Keep human commentary for the moments that need pacing and selectivity. The comment study found human comments stronger on timing and helpfulness, so reserve instructor voice for the frames where timing carries meaning.
- Treat avatars as a production decision with costs (labor, environmental, integrity) rather than as a neutral efficiency win.

For developers

- Instrument comprehension, not only watch-through and satisfaction. If you ship ten variants, report which ones improved unassisted understanding.
- Match comment *structure* to the instructor benchmark in your evaluation, not just semantic relevance or density — the diversity gap is where generated commentary visibly fails.
- Expose the generative status of avatars and personalized variants; presenting synthetic presence as instructor presence is an integrity question before it is a design question.

For researchers

- Report preference and outcome measures together, and state plainly when a study has only the first.
- Report temporal alignment explicitly, given that misalignment between video content and cognitive processing shows up in the neural data.

Learning theories and processes

Learning Theories

> **Learning Theories** — the family of frameworks that explain how learning happens, and the umbrella concept for the knowledge base's theory-related ideas. In AI in education, learning theories shape both how AI systems are designed (the pedagogy they embody) and how the field interprets whether AI "works": the same tool can be a scaffold under Constructivism assumptions, a reinforcement engine under Behaviorism, or a cognitive-load hazard under Cognitive Load Theory.

Questions to Consider

- Think about an AI tutor or adaptive system you have used or seen. What assumptions did it make about how people learn — did it reward right answers (behaviorism), build understanding (constructivism), or manage mental effort (cognitive load)? Did its makers ever state those assumptions?
- The page describes a recurring gap: discourse espouses constructivism while AI implementations default to drill-and-feedback mechanics. Where have you seen a tool claim to support deep learning but actually just reinforce surface responses?
- The same AI tool can look like success under one theory and failure under another — inflated homework scores read as learning under behaviorism but as a failure to build durable understanding under constructivism. Which lens is fairer for judging whether students actually learned?
- Because every AI tutor embeds a theory whether its designers say so or not, 'does it work?' may be the wrong question. What is the better question to ask about an educational AI, given the theories it could embody?
- Generative AI is prompting educators to consider new theories — like learning as iterative co-construction between humans and AI, or AI as a cognitive partner across the lifespan. Does the rise of AI genuinely require new learning theories, or do existing ones still suffice?
- Learning-gains measurement is itself 'theory-laden': an instrument built on one theory may not capture the gains another predicts. How might two researchers with different theoretical commitments look at the same data and reach opposite conclusions about whether an AI tool worked?

Introduction

This is the umbrella concept for the knowledge base's learning-theory strand. Learning theories sit at the heart of AI in education because every AI tutor, adaptive system, and feedback tool embeds assumptions about how people learn — whether the designers state them or not. The knowledge base documents these theories individually and treats them as the conceptual lens through which AI's design and effects are evaluated. The research field that tests those frameworks is a separate page: the learning sciences study learning empirically — experiments, classroom trials and design-based research — and treat a theory as

something to be confirmed or falsified, whereas this page collects the frameworks themselves. The two phrases are kept distinct in this knowledge base, the singular “learning science” naming this theory strand.

The learning-theory landscape

The knowledge base documents several families of learning theory, each with its own concepts:

- **Classical learning theories.** Behaviorism (learning as observable behavioral change through reinforcement and drill-and-practice) and constructivism (learning as active knowledge construction) are the two poles that recur most often in AI research. The field frequently exhibits a “constructivism in name, behaviorism in practice” gap, where discourse espouses construction but AI implementations default to drill-and-feedback mechanics.(Artificial intelligence in vocational education and training: A systematic review of educational purposes, theoretical conceptualizations, and empirical effectiveness) cognitivism is the third classical pole — learning as a change in internal mental representations — and the theory most responsible for AIED’s signature contributions (Knowledge Tracing, Cognitive Diagnosis, Learner Modeling and Adaptive Instruction, Intelligent Tutoring).
- **Sociocultural and developmental theories.** Sociocultural Learning holds that learning and development arise through social participation and are mediated by cultural tools and more knowledgeable others — spanning the Zone of Proximal Development, Scaffolding, apprenticeship, communities of practice, and distributed cognition. In the AI age, generative AI is increasingly framed as a *mediational agent* that both mediates activity and generates contingent contributions to interaction.(Generative AI as a Mediational Agent: Rethinking Learning in Sociocultural Theory)
- **Cognition and cognitive architecture.** Cognitive psychology / cognitivism is the umbrella for this family: Cognitive Load Theory (how working-memory limits shape instruction), Dual-Process Theory (fast intuitive vs. slow deliberative processing), and Metacognition (monitoring and regulating one’s own learning) explain the *internal* mechanisms that AI tools engage or bypass.
- **Motivation and self-direction.** Self-Determination Theory (autonomy, competence, relatedness), Self-Efficacy (confidence in one’s capability), Self-Regulated Learning (goal-setting, monitoring, and adjustment), and Motivation explain why learners engage with AI the way they do.
- **Learning context and activity.** Experiential Learning, Active Learning, Project-Based Learning, Collaborative Learning, Transfer of Learning, Desirable Difficulties, and Embodied Learning describe the kinds of activity and context that produce durable learning.

Learning theories and learning gains

Learning theories are ultimately evaluated by their outcomes, and the knowledge base’s Learning Gains concept is where theory meets evidence. Each theory makes a different prediction about what *counts* as learning and how to measure it: behaviorism predicts observable performance gains on drill-and-feedback tasks; constructivism predicts deeper understanding that transfers to novel problems; sociocultural theory predicts gains in participation and mediated Problem Solving; and cognitive-load theory predicts gains only when instruction respects working-memory limits. Measurement choices, then, decide which theory’s prediction an evaluation can confirm. In the AI era, the sharp divergence between AI-assisted performance

and unassisted learning gains (see Faster Completion, Less Learning: Generative AI Reduced Study Time on Math Problems and the Knowledge They Build, The generative AI learning penalty: Evidence from Chinese secondary education) can be read through this lens: a behaviorist reading sees inflated homework scores as success, while a constructivist reading, focused on durable understanding, sees the same evidence as a failure to learn.

The pooled evidence is positive, and it measures a narrower construct than the theories do. A PRISMA meta-analysis of 53 studies puts GenAI assistance at g = 0.40 on academic achievement, 0.72 on higher-order thinking, 0.76 on writing and 0.81 on motivation, with GenAI feedback the largest mechanism at g = 1.27 (Dong (2026)). Those are gains on the instruments the included studies chose, so they settle a behaviorist or cognitivist reading of "it works" and leave the constructivist prediction about durable, transferable understanding untested. The country subgroups also diverged, from China's g = 0.71 to Turkey's nonsignificant g = 0.01, so the pooled estimate is an average to test locally rather than a property of the tool.

Why learning theories matter for AI in education

Learning theories matter for three reasons:

- **They predict AI's effects.** Whether an AI tool improves or harms learning depends on which mechanism it activates. A tutor that gives away answers harms under a constructivist lens (it bypasses construction), is neutral under behaviorism (it reinforces), and raises cognitive-load concerns (it offloads rather than builds). The knowledge base's Cognitive Offloading and Over-Reliance concepts capture the risk side of this.
- **They expose the theory-practice gap.** Empirical work repeatedly finds that AI implementations embody different theories than the discourse claims — most notably constructivist language paired with behaviorist drill-and-practice mechanics.(Artificial intelligence in vocational education and training: A systematic review of educational purposes, theoretical conceptualizations, and empirical effectiveness) Evaluating AI therefore requires asking *which* theory a system actually embodies, not just whether it "works."
- **They are being actively rethought.** Generative AI is prompting educators to revisit whether the classical theories suffice. Generativism proposes that learning in the AI age increasingly occurs through iterative co-construction between human learners and AI systems, extending rather than replacing the classical four (behaviorism, cognitivism, constructivism, connectivism). (Generativism: Toward a Learning Theory for the Age of Generative Artificial Intelligence)

New theoretical directions from recent AIED work

Recent theoretical work extends the classical strand in several directions, each re-centering the human–AI relationship rather than treating AI as a neutral tool:

- **Human–AI co-AI Regulation in Education.** A developmental framework positions AI not as an external instrument but as a **cognitive partner** that co-regulates thinking, learning, and self-control across the lifespan.(Artificial intelligence as a cognitive partner: a developmental framework for human-AI co-regulation in learning) Drawing on executive function, Metacognition, distributed cognition, and sociocultural development, it casts AI in four roles —

scaffold, metacognitive support, external memory / Cognitive Offloading system, and decision partner — with the framework most relevant from middle childhood onward.

- **Ensemble Cognition.** A philosophical framework reconceptualizes thinking as emerging from dynamic interactions between human and artificial agents rather than residing solely in individual minds.(Towards a philosophy of ensemble cognition: Reconceptualising agency and mind in AI-mediated educational environments) It challenges the "consciousness paradigm" (the autonomy, consciousness, and stability assumptions) and articulates five features — distributed agency, dynamic centrality, cognitive orchestration, multi-representational integration, and context-sensitive switching — while distinguishing AI's **functional agency** from moral responsibility.
- **Self-Directed Growth / A2PL.** An extension of self-directed learning integrates Generative AI with learning analytics to cultivate **Self-Directed Growth**, operationalized through the Aspire to Potentials for Learners (A2PL) model.(Fostering Self-Directed Growth with Generative AI: Toward a New Learning Analytics Framework) It reconfigures learner aspirations (humanistic), complex thinking (constructivist), and Self-Assessment (pragmatic) into a single competency, positioning GAI as a non-prescriptive collaborative scaffold rather than a content provider.
- **Deceptive overgeneralization.** An, McLaren, and Stamper (2026) extend the ACT-R / Knowledge-Learning-Instruction tradition by theorizing when observed correctness masks incomplete conditional understanding: learners compile an overgeneralized production that omits an application constraint yet still performs correctly — a failure mode that adaptive mastery systems, and even traditional instruction, can miss unless they test *when to withhold* an action.
- **Executable KLI theory.** Rachatasumrit, Koedinger & Carvalho (2025) ground the Knowledge-Learning-Instruction framework in an executable computational model (the Apprentice Learner framework with an ACT-R-style memory mechanism) that reproduces a cross-over interaction in human data: pure practice aids verbatim fact memory (by delaying forgetting) while example-integrated practice aids generalizable skill induction. Because KLI ties constant (fact) knowledge to memory processes and variable (skill) knowledge to induction, the result is a predicted content–treatment interaction rather than a contradiction between testing and worked-example recommendations — and the model's success only when a memory mechanism is present demonstrates that practice and examples play distinct, complementary roles.
- **Embodiment as an ontological challenge to AI's paradigm.** Videla, Penny and Ross (2026) argue an ontological divide separates embodied, enactive cognition from the representational idiom AI embodies, so AI should be decentered as the epistemic center rather than treated as a neutral tool.

How the knowledge base organizes this strand

Rather than treating learning theories as abstract philosophy, the knowledge base grounds each in the AI-in-education research that uses it. The Constructivism and Behaviorism pages document how AI designs embody (or betray) each theory; Cognitive Load Theory, Self-Regulated Learning, Metacognition, and Transfer of Learning connect theory to specific AI mechanisms and outcomes. This mirrors how the knowledge base treats other umbrella domains like Feedback and Assessment — a coherent system of interacting concepts rather than isolated pages.

Learning theories and "education about AI"

Learning theories also appear as content in AI literacy curricula: learners study behaviorism, cognitivism, constructivism, and connectivism to understand the pedagogical assumptions behind the tools they use. (Generativism: Toward a Learning Theory for the Age of Generative Artificial Intelligence) Teaching this strand gives students (and educators) the vocabulary to critique why an AI product is built the way it is — and whether its mechanics serve the learning goal at hand.

- **The mediational agent.** Warschauer, Tate, and Ritchie (2026) argue generative AI breaks the sociocultural distinction between mediational means and social interaction, proposing the *mediational agent* — a system that both mediates action and generates contingent, non-accountable contributions, occupying a hybrid space between a tool and a social partner. This yields five human-first habits of participation (primacy of human cognition, purposeful engagement, supervisory agency, epistemic vigilance, reflective self-regulation).(Generative AI as a Mediational Agent: Rethinking Learning in Sociocultural Theory)

Theories proposed for the AI era

Alongside the classical families, the knowledge base documents theories written specifically for learning with AI systems, and these carry the design implications that the older theories leave open. Agentivism (Yan and Gašević 2026) is a mid-range example: it defines learning as durable growth in human capability rather than successful task completion, names four mechanisms (delegated agency, epistemic monitoring and verification, reconstructive internalization, and transfer under reduced support), and states six testable propositions, among them that AI support preserving learner responsibility for problem framing, criteria setting and justification produces stronger learning than support that delivers answers.

Elsayed (2026)'s **Pedagogical Symbiosis** makes a stronger ontological claim: the learner is a *Post-Human* entity whose cognition is hybrid rather than tool-assisted, organized by four principles: cognitive offloading and augmentation, epistemic co-construction, metacognitive symbiosis, and dynamic identity formation; operationalized as a Symbiotic Portfolio rubric and a "Cognitive Choreographer" teacher role; it is explicitly untested.

Common Misconceptions

"One of the learning theories is the correct one, so theory choice is a matter of taste." The theories make different claims about what counts as evidence, so the same data can support opposite conclusions. The clearest instance: inflated homework scores read as **learning under behaviorism** and as **a failure to build durable understanding under constructivism**. Theory choice therefore determines whether an intervention succeeded, which makes it a measurement decision rather than a stylistic preference.

"A tool that supports deep learning will look like deep learning under any framework." It will look like success under one and failure under another, as above. That is why the field's outcome measures need to be justified against a stated theory rather than borrowed as if neutral.

"More theories mean a better-understood field." Accumulation without adjudication is the opposite of progress. Theories proposed for the AI era multiply faster than they are tested, and the sign of maturity is

competing predictions being resolved — which requires designs that can distinguish them, not catalogues that accommodate them.

“Education about AI is the same as AI in education, theoretically speaking.” They draw on different strands: one asks how learners come to understand AI as a subject, the other how AI changes how learning happens. Conflating them produces literature reviews that mix two distinct evidence bases and report a coherent picture of neither.

Implications for Practice

For instructors

- Choose theory by what you need it to do: explain how learning happens, describe the learner’s state, or explain why a practice spreads. Applying the wrong layer measures the right variable against the wrong prediction.
- State the outcome measure’s theory commitment explicitly, since inflated homework scores read as success under behaviorism and as failure under constructivism from identical data.
- When a framework cannot predict a difference between configurations, it cannot be tested in your setting and will not help you decide.

For developers

- Publish the theory your system embodies and the prediction that would falsify it; “grounded in constructivism” without a falsifiable difference is a claim with no content.

For researchers

- Design for adjudication between theories rather than accumulation of frameworks. Maturity shows up as competing predictions resolved, not as vocabulary growth.

Connected FAQs

- What Are Notable Gaps in the Research Literature on AI in Education?

Behaviorism

> **Behaviorism** — the learning theory that treats learning as a change in observable behavior produced by stimulus–response associations and reinforcement, rather than by changes in internal mental states. In AI in education, behaviorist principles underlie the drill-and-practice, immediate-feedback, and adaptive-pacing designs that dominate many Intelligent Tutoring and Adaptive Learning systems.(Artificial intelligence in vocational education and training: A systematic review of educational purposes, theoretical conceptualizations, and empirical effectiveness)

Questions to Consider

- Behaviorism treats learning as a change in observable behavior driven by stimulus-response and reinforcement — not by internal mental states. Before reading, which educational experiences in your own past were built on reward, repetition, and immediate feedback? What did they succeed at, and what might they have missed?
- A surprising finding on this page is that even where educational discourse espouses rich constructivist theories, actual AI implementations are predominantly behaviorist — drill-and-practice, immediate feedback, adaptive pacing. Why do you think behaviorist mechanics dominate in practice despite being out of fashion in theory?
- The page warns of an educational 'Turing Trap' — using AI to replicate rather than augment human instruction. If an AI system optimizes for correct responses and efficiency, what might it quietly optimize away in a learner's active knowledge construction?
- Behaviorist designs are described as powerful for foundational fluency — vocabulary, arithmetic, code syntax — but inadequate for higher-order, conceptual, or agentic learning on their own. Where in your own learning would a drill-and-practice AI help, and where would it actively hurt?
- The design question posed is not whether behaviorism is 'right' but whether a given system's mechanics serve the learning goal. How would you tell whether an AI tutor's immediate-feedback, adaptive-pacing design is building genuine transferable understanding or just making observable performance look good?

Introduction

Behaviorism holds that learning is the strengthening or weakening of stimulus–response connections through reinforcement, and that unobservable mental constructs are poor explanations of learning. Its applied legacy in education is **programmed instruction and drill-and-practice**: presenting content in small steps, eliciting a response, and immediately reinforcing correct answers. These principles map cleanly onto the mechanics of Adaptive Learning and Intelligent Tutoring systems, which adapt pacing and difficulty to student responses and provide immediate feedback.

Core ideas

- **Learning is behavioral change.** The target is a measurable change in performance, not an internalized understanding. This makes behaviorist designs natural for observable outcomes like fluency, speed, and accuracy.
- **Reinforcement drives learning.** Correct responses are reinforced and errors corrected, typically with immediate feedback — a design pattern ubiquitous in AI tutoring and drill systems.(Artificial intelligence in vocational education and training: A systematic review of educational purposes, theoretical conceptualizations, and empirical effectiveness)
- **Small steps and scaffolding by pacing.** Instruction is broken into incremental units with feedback at each step, analogous to the way adaptive systems sequence practice.
- **Small steps are a design assumption, and a randomized test of pacing ran against it.** With 199 US college students, feedback sequenced as encouragement, then hints, then the answer produced worse learning than full-solution feedback delivered immediately, though students found the sequenced version more encouraging. The affective gain was canceled by a behavioral pathway, more resubmissions per task, and the net effect was poorer learning (Assessing the Impact and Underlying Pathways of Sequenced AI Feedback on Student Learning).
- **The learner is largely passive in knowledge construction.** The environment (or system) structures and rewards responses; the learner responds rather than constructs meaning — the direct opposite of Constructivism assumptions.

Behaviorism and AI in education

Behaviorist designs dominate practice

Empirical work repeatedly finds that actual AI implementations are predominantly **behaviorist or cognitively oriented** — emphasizing drill-and-practice, immediate Feedback, and adaptive pacing — even where discourse espouses richer theories. A systematic review of AI in vocational education and training (VET) concluded that constructivist theories are espoused in VET discourse while **behaviorist AI implementations dominate in practice**, and warned of an educational "Turing Trap" in which AI replicates human instruction instead of augmenting it.(Artificial intelligence in vocational education and training: A systematic review of educational purposes, theoretical conceptualizations, and empirical effectiveness)

Output equivalence: when behavior no longer certifies learning

Behaviorism defines learning as a change in observable behavior, which makes it the theory most directly embarrassed by generative AI: a learner can now produce an essay, an analysis, or working code indistinguishable from the work of someone who holds the competence the artifact is supposed to certify. The observable behavior is identical while the learning may not have occurred, a failure mode Generativism calls the behavioral equivalence problem.

The gap between performance and learning is not new, but AI widens it. In a field experiment with nearly a thousand high school mathematics students, unrestricted access to a standard assistant raised practice performance by 48 percent while the same students later scored 17 percent below peers who had practiced

without AI on an unassisted exam; a guardrailed tutor version largely removed that deficit (Distinguishing performance gains from learning when using generative AI). Read behaviorally, the lesson is about measurement rather than Pedagogies and Teaching Strategies: a system that optimizes for the output can satisfy the theory's own criterion of learning while failing its purpose.

The tension with constructivism and agency

The behaviorist emphasis on response-and-reinforcement sits in direct tension with Constructivism, Self-Regulated Learning, and Learner Agency goals. When AI systems optimize for correct responses and efficiency, they can under-serve the learner's active knowledge construction, critical reflection, and autonomous decision-making. This is the same gap flagged in the Constructivism "constructivism in name, behaviorism in practice" pattern — and it connects behaviorism to debates about Cognitive Offloading and Over-Reliance when AI does the cognitive work for students.

Where behaviorist designs still fit

Behaviorist principles remain well suited to: - **Foundational skill and fluency building** — where repetition and immediate feedback measurably improve automaticity (e.g., vocabulary, arithmetic, code syntax). - **Adaptive Learning and Intelligent Tutoring** — which rely on step-wise practice, response-driven pacing, and immediate feedback.(Artificial intelligence in vocational education and training: A systematic review of educational purposes, theoretical conceptualizations, and empirical effectiveness) - **Low-stakes Formative Assessment** and drill in well-defined domains where the target outcome is observable and the path to it is largely procedural.

The design question is not whether behaviorism is "right" but whether a given AI system's behaviorist mechanics serve the *learning goal* — for procedural fluency they can be powerful; for higher-order, conceptual, or agentic learning they are inadequate on their own.

Behaviorism and "education about AI"

Behaviorism also appears in how learners encounter AI as a topic. The theory is one of the four dominant learning theories — behaviorism, cognitivism, constructivism, and connectivism — that generative AI is prompting educators to revisit. (Generativism: Toward a Learning Theory for the Age of Generative Artificial Intelligence) It is also referenced in cooperative-learning and design contexts as part of the theoretical backdrop learners are taught.(Artificial intelligence assisted design of a novel cooperative learning technique for higher education) Understanding behaviorism helps learners see why many AI tools (and the products built on them) are designed for response-and-reinforcement rather than for deeper construction.

Implications for design and research

1. **Match mechanics to goals.** Behaviorist drill-and-feedback designs suit procedural fluency and observable outcomes; they are a poor fit for conceptual, transferable, or agentic learning goals on their own.

2. **Watch the theory-practice gap.** Researchers should check whether an AI implementation's behaviorist mechanics are serving the espoused learning goal or quietly replicating the "Turing Trap" of AI as an answer machine.(Artificial intelligence in vocational education and training: A systematic review of educational purposes, theoretical conceptualizations, and empirical effectiveness)
3. **Pair behaviorism with richer scaffolds.** Immediate-feedback designs are most effective when embedded in a broader Scaffolding and Self-Regulated Learning context, rather than standing alone as pure drill.
4. **Evaluate observable *and* transferable outcomes.** Behaviorist success criteria (speed, accuracy) should be complemented by measures of whether learning transfers and generalizes, per Transfer of Learning and Research Methods in AIED.

Common Misconceptions

"Behaviourism is obsolete, so its influence on AI in education is a historical footnote." Behaviorist mechanics dominate practice while being out of fashion in theory — reinforcement loops, streak counters, immediate correct/incorrect feedback and mastery gating are the default architecture of most deployed systems. Dismissing the theory while shipping its mechanisms is the field's most widespread inconsistency, and it means the critique is not academic.

"Observable behaviour change certifies learning." That is precisely what AI breaks. Output equivalence is the failure mode: when a model can produce the behavior the system rewards, the observed response no longer certifies the internal change behaviorism inferred it from. A behaviorist design is only as valid as the assumption that the behavior had to be produced by the learner, and generative AI removes that assumption without changing the design.

"Behaviourist designs are simply inferior to constructivist ones." They fit specific targets well — fluency, factual recall, procedural automaticity — where immediate feedback and repetition are genuinely what the task requires. The error is not the mechanism; it is using a mechanism whose validity condition (the learner must produce the response) has silently stopped holding.

"Because the theory is discredited, systems built on it can be judged by outcomes alone." Outcomes are exactly what output equivalence corrupts. A system can report excellent behavioral outcomes while the learning has moved elsewhere, so behaviorist-influenced systems need the unassisted measure more than any other kind.

Constructivism

> **Constructivism** — the learning theory that knowledge is actively built by the learner through experience, reflection, and interaction, rather than passively received from an instructor or system. In AI in education, constructivism underlies the design commitment that AI tools should support learners' own knowledge construction — prompting, questioning, and Scaffolding — rather than perform the cognitive work for them.(Artificial intelligence in vocational education and training: A systematic review of educational purposes, theoretical conceptualizations, and empirical effectiveness)(Generative AI (GenAI) as a mindtool that supports generative learning (GL))

Questions to Consider

- Have you ever 'learned' something in class only to realize you couldn't actually explain or use it later? What was missing — and what does that tell you about how real understanding forms?
- Constructivism claims knowledge is built, not transmitted. If that's true, what happens when an AI tutor simply supplies the correct answer?
- The phrase 'constructivism in name, Behaviorism in practice' describes AI tools that claim to support active learning but actually run drill-and-practice. Have you seen this gap? How would you detect it in a tool you're evaluating?
- Papert's constructionism says we learn most powerfully by building shareable artifacts. In the AI era, one framework puts it as: 'the AI writes the code, but the student writes the model.' What is a student actually constructing when AI handles the mechanics?
- Some AI tools practice 'generative refusal' — withholding answers and posing questions instead. When would deliberately withholding help be more pedagogically valuable than providing it?
- If knowledge is constructed, then AI literacy isn't learned by hearing lectures about AI — it's learned by using, critiquing, and building with AI. What does that imply about how AI literacy should be taught to you or your students?

Introduction

Constructivism is a family of theories rather than a single doctrine, but its core claim is shared: learners do not absorb meaning; they construct it. Understanding in this view is not the accumulation of transmitted facts but the active organization of experience into mental models. This has direct implications for how AI in education should be designed, evaluated, and taught — and it helps explain both the promise and the risk of generative AI in the classroom.

Mishra et al. contrast Papert's constructionism (Logo, microworlds, debugging-as-learning) with Anderson's cognitive tutors as competing visions of creative agency vs. systematic control in AIED history.

Core ideas

- **Knowledge is constructed, not transmitted.** Learners build understanding by acting on the world, reconciling new information with prior knowledge, and reflecting on the results. An AI tutor that simply supplies correct answers bypasses the constructive activity that produces durable understanding.(Stop Writing for Me: Generative Refusal in AI Tools for Thought)
- **Prior knowledge shapes new learning.** New ideas are interpreted through the learner's existing mental models, so instruction must surface and build on what learners already know — a principle directly relevant to Misconceptions about AI and to AI tutors that adapt to the learner.
- **Social interaction supports construction.** A major strand — social constructivism — holds that meaning is co-constructed through dialogue, collaboration, and culturally situated activity. This connects constructivism to Collaborative Learning and to Socratic Method approaches in which AI prompts rather than dictates.(Enacting Constructive Conflicts with AI Agents to Enhance Reconsideration among Novice Interaction Designers)
- **Construction is visible in activity.** Learners reveal (and consolidate) their understanding by generating, explaining, and producing — which is why the ICAP framework ranks "constructive" and "interactive" engagement above "active" and "passive" modes.(Systematic review of collaborative learning activities for promoting AI literacy)(Measuring Cognitive Engagement in Collaborative Discourse with an Extended ICAP Framework: Comparing Human Annotation, In-Context Learning, and Reflective LLM Agents) A boundary on the theory is that constructivism presumes human-centered epistemic agency, which leaves it short of accounting for an AI that simulates reasoning and co-constructs meaning; the proposed supplement is epistemic co-agency, in which learners treat AI output as contestable and keep epistemic sovereignty over what counts as knowledge (Samuel (2026)).

Constructionism

Constructionism is the branch of constructivism associated with Seymour Papert that adds a specific claim: learning happens most powerfully when learners construct *external, shareable artifacts* — physical or digital objects they design, build, and debug. Where Piagetian constructivism focuses on the internal mental construction of knowledge, constructionism holds that this construction is best supported and made visible through making something tangible (Harel & Papert, 1991). In AIED history, constructionism stands as the "agency" pole of the field's central control-vs-agency tension, set against Anderson's structured cognitive tutors.

- **Logo and microworlds.** Papert co-developed Logo (1967) with its iconic "turtle" — a programming microworld where children explore geometry and other powerful ideas by commanding and debugging a visible agent. Debugging is reframed as a natural, valuable part of learning, not failure.(Control vs. Agency: Exploring the History of AI in Education)
- **Construction over instruction.** Constructionism critiques "instructionism" — the assumption that teaching is the efficient transfer of knowledge — and instead positions learners as autonomous agents who construct understanding through projects and experimentation (Papert, 1980, *Mindstorms*).

- **Lineage into modern edtech.** Logo's emphasis on creative, hands-on construction underpins Game-Based Learning, Project-Based Learning, robotics (LEGO Mindstorms, Scratch, programmable bricks), and the broader maker movement.
- **The constructionist legacy in AI.** Constructionism implies AI tools should serve as **materials to build with** — thinking tools and creative co-constructors that the learner directs — rather than as answer-providing instructors. This is the direct ancestor of the knowledge base's mindtool framing of generative AI and of design commitments that preserve learner agency over the learning process.(Pathways to Learning: Exploring High School Students' Learning of AI-Powered Educational Robotics)
- **Constructionism in the GenAI era: learn by writing the model, not the code.** The arrival of code-generating AI has *renewed* constructionism as a design response rather than weakening it. Gousopoulos's **Code-to-Learn with Generative AI (CtL-GenAI)** framework synthesizes constructionism, cognitive-load theory, Self-Regulated Learning, the ICAP engagement model, productive failure, and sociocultural scaffolding for upper-secondary students building software with AI. Its organizing claim — **"the AI writes the code, but the student writes the model"** — reframes the construction target: when GenAI does the syntactic work of writing code, the learner's construction shifts to building and debugging the *conceptual model* the code expresses. CtL-GenAI defines model authorship as a construct with four facets and ordered levels carrying observable indicators, and formalizes a partial-credit, falsifiable measurement model to test whether such learning actually occurs.(Code to Learn with Generative AI: A Theoretically Grounded Framework for Artifact Construction in Upper-Secondary Education)(The AI writes the code, the student writes the model: A theory and measurement programme for learning by construction with generative AI) This is constructionism's classic "make something shareable and debug it" updated so that the artifact the student makes and reflects on is a mental model made visible, not merely source code — and it couples the theory to an explicit measurement program so the claim becomes empirically testable.

Constructionism is thus both a learning theory and a critique: it insists that the purpose of education is not to reproduce existing knowledge structures but to empower learners to construct and transform them — a stance with clear implications for whether AI in education reinforces or challenges established hierarchies.

Constructivism and AI in education

AI for constructivist learning

Well-designed AI can enable construction at scale. Intelligent Tutoring and AI Tutoring systems can pose problems and guide Help-Seeking instead of giving away answers; Simulation and Game-Based Learning environments let learners build and test mental models; and Project-Based Learning and Experiential Learning activities supported by AI give learners authentic construction tasks. The central design pattern is **Scaffolding** — calibrated support that fades as competence grows — rather than completion.(The Path to Conversational AI Tutors: Integrating Tutoring Best Practices and Targeted Technologies to Produce Scalable AI Agents)(Embodied inquiry with AI as facilitator: An exploratory case study)

Classifying the *questions learners ask* is one way to see construction happening, and to act on it. Lee, Atif & Kang (2026) sort 434 authentic learner questions from 11 IT students across 12 courses into three constructivist instructional roles — knowledge transmitter, facilitator, and co-learner — and train four transformers to recognize them. DeBERTa classified factual knowledge-transmitter questions at 96.67% precision but facilitator questions at only 78.79%, and every model confused the two higher-order roles most often: detecting dialogic, exploratory inquiry is far harder than detecting information-seeking. Because the typology treats questions as diagnostic evidence of epistemic engagement rather than as mere inputs, it supports a distinctly constructivist design move — when a learner repeatedly asks only factual questions, the system can prompt reflective, exploratory questioning that develops Metacognition and critical inquiry rather than answering at whatever depth the learner's question implies.

The risk of "constructivism in name, behaviorism in practice"

Empirical work repeatedly finds a gap between espoused constructivist goals and actual AI implementations. A systematic review of AI in vocational education, for instance, found that constructivist theories are espoused in VET discourse while **behaviorist drill-and-practice designs dominate in practice**, and warned of an educational "Turing Trap" — using AI to replicate rather than augment human instruction.(Artificial intelligence in vocational education and training: A systematic review of educational purposes, theoretical conceptualizations, and empirical effectiveness)

This pattern generalizes across the field:

- When generative AI completes writing, reasoning, or code for students, the learner loses the constructive thought process the task was designed to build — the concern central to Cognitive Offloading and Over-Reliance.(Stop Writing for Me: Generative Refusal in AI Tools for Thought)
- The loss is now measurable, and it follows the work rather than the tool. In 26,811 Chinese secondary students, generative AI raised homework scores by 18% and cut completion time by 30%, while closed-book exam scores fell 20% within six months. The decline concentrated among the roughly 81% of users whose completion times indicated homework outsourcing, and users who kept homework time comparable to non-users learned as efficiently (Strömberg, Lei and Wu (2026)). The variable that predicted learning was not AI use but whether the learner still performed the construction.
- AI implementations that emphasize adaptive feedback and efficiency frequently under-serve the learner-agency, critical-reflection, and autonomous-decision goals that constructivism implies. (Artificial intelligence in vocational education and training: A systematic review of educational purposes, theoretical conceptualizations, and empirical effectiveness)

The naming trap: generative AI output is not generative learning

A recurring confusion in the field turns on a name collision. **Generative AI** names a class of *technology* — models that generate text, images, or code. **Generative learning** (Wittrock's generative-learning theory) names a *learner activity* — the learner actively making meaning by constructing connections between new information and prior knowledge, through strategies such as summarizing, mapping, drawing, self-testing, and self-explaining. The two are not the same thing, and conflating them has real pedagogical consequences: an AI *producing* a summary or a map for the student is the opposite of the student *performing* the generative-

learning act. Dabbagh & Fake (2026) build directly on this distinction, arguing that a GenAI mindtool supports generative learning only when the *learner* drives the constructive activity — generating a mind map with AI assistance is generative learning; having the AI generate the map wholesale is not, however fluent or correct the output.

The deciding question is **who performs the meaning-making**: - Does the student construct an explanation, or merely receive one? - Does AI prompt the learner to connect ideas, or supply the connections for them? - Is the artifact (summary, map, code, model) the *product* of the learner's construction, or a substitute for it?

This mirrors the ICAP hierarchy — constructive and interactive engagement outrank active and passive — but sharpens it: a tool can produce visibly "constructive-looking" output while the learner sits in a *passive* or *active* mode. Evaluating a GenAI tool for generative learning therefore means inspecting where the constructive effort actually happens, not whether generative output is present. This is the same constructivist-in-name / behaviorist-in-practice trap, applied to the specific case of generation: model authorship (the AI writes the code, the student writes the model) is one concrete resolution — the learner constructs the *conceptual model* even when AI supplies the surface artifact.

Design responses grounded in constructivism

- **Generative Refusal** — AI tools that strategically withhold generated text and pose questions instead, returning cognitive friction to the user so that the labor of articulation itself builds understanding.(Stop Writing for Me: Generative Refusal in AI Tools for Thought)
- **Thinking tools over answer machines** — using GenAI as a Generative AI (GenAI) as a mindtool that supports generative learning (GL) in which the learner drives the tool, rather than the tool replacing the learner.(Generative AI (GenAI) as a mindtool that supports generative learning (GL))
- **Constructive conflict** — adversarial AI agents that challenge a learner's design or reasoning, prompting reconsideration and deeper construction of alternatives, in the tradition of Socratic tutoring.(Enacting Constructive Conflicts with AI Agents to Enhance Reconsideration among Novice Interaction Designers)
- **Simulated opposition is not opposition.** A counter-position that can be voiced on demand but never resists rehearses the choreography of dialogue while withholding what makes it potent: it has no embodiment, stake, or exposure to consequence, so unlike a human other it offers no route to repair (Du et al. (2026)).
- **Internal feedback via comparison** — having learners compare their own work against AI-generated exemplars so that the act of comparison itself generates learning.(Unravelling undergraduates' development of evaluative judgments through AI-supported internal feedback)
- **Question-type-aware prompting** — classifying learner questions into constructivist roles so the system can deliberately escalate a student from information-seeking toward exploratory, dialogic inquiry instead of mirroring whatever cognitive depth the question implies. Because facilitator and co-learner intent remain confusable for automated classifiers, this design keeps a human validating the categorization before it drives Feedback or Scaffolding.(Analysing AI utilisation in education through learner question types: A constructivist approach)

- **Community as the evaluative standard** — learners design something real for their community using AI as a design resource, while community knowledge and community practitioners serve as the standard that judges the outcome, leaving room for limitation, refusal, or strategic non-use where critical engagement requires it.(Ojeda-Ramirez, Gyles & Peppler (2026))

Constructivism and "education about AI"

Constructivism also shapes how AI literacy itself is taught. If knowledge is constructed, then AI literacy is not acquired by lecturing about models but by actively using, critiquing, and building with AI — generating artifacts, interrogating outputs, and reflecting on the interaction.(Systematic review of collaborative learning activities for promoting AI literacy) This positions AI Literacy as an active, participatory competency rather than a body of passive knowledge, and it connects constructivism to Critical Thinking and to Learner Agency in learners' encounters with AI.

Implications for design and research

1. **Preserve the constructive activity.** AI should scaffold the learner's own thinking — prompt, question, and support — rather than perform it. Designers should ask whether the tool increases or replaces the learner's constructive effort.(Stop Writing for Me: Generative Refusal in AI Tools for Thought)
2. **Use the ICAP lens.** ICAP classifies engagement into constructive, interactive, active, and passive modes — use it to evaluate whether AI interactions actually elicit constructive and interactive modes rather than passive consumption. Designers should favor the deeper (constructive and interactive) modes where the learning goal warrants.(Systematic review of collaborative learning activities for promoting AI literacy)
3. **Align theory and implementation.** Researchers should look beyond whether AI "works" to *how* it embodies a learning theory, checking for the constructivist-in-name, behaviorist-in-practice gap. (Artificial intelligence in vocational education and training: A systematic review of educational purposes, theoretical conceptualizations, and empirical effectiveness)
4. **Study learner agency and transfer.** Constructivist commitments imply evaluating not just immediate test gains but whether learners can transfer and independently apply their constructed understanding.(Research Methods in AIED)

Common Misconceptions

- **"You can detect constructivist teaching from the questions asked."** A DeBERTa classifier **classified factual knowledge-transmitter questions at 96.67% precision but facilitator questions at only 78.79%**, and **every model confused the two higher-order roles**. The construct that matters most is the one automated detection handles worst.
- **"Surface features of a lesson reveal its pedagogy."** The classifier's failure is not an implementation detail. Facilitator and constructivist roles are the hard cases precisely because they are defined by what the teacher does with the learner's thinking, and that relation is not recoverable from the question text alone.

- **“Constructivism means the teacher does not explain.”** The theory locates learning in the learner’s construction from experience, which is compatible with direct instruction. Treating it as a prohibition on telling misreads both the theory and the evidence on worked examples.

Cognitive Psychology

> **Cognitive psychology / cognitivism** — the family of theories that explain learning through internal mental processes — attention, perception, memory, reasoning, and metacognition — rather than through observable behavior alone. In AI in education, cognitivist assumptions underpin the field's most distinctive contributions: Intelligent Tutoring systems that model learner knowledge, Knowledge Tracing and Cognitive Diagnosis that track what a learner knows, Feedback designs grounded in error diagnosis, and the whole learner modeling and adaptive instruction family. Cognitivism is the middle ground between Behaviorism (learning as behavioral change) and constructivism (learning as active meaning-making), and it is the theoretical lens most closely tied to the computer metaphor of the mind that animated early AIED.

Questions to Consider

- When you think about 'learning,' do you picture a change in what someone does, or a change in what they know and can retrieve? How might that distinction change how you judge whether an AI tutoring tool actually works?
- AI tutoring is built on a 'computer metaphor' — treating the mind as an information-processing system with memory limits. Where does that metaphor feel powerful, and where might it miss something important about how humans learn?
- An AI tool makes a task feel effortless: it explains the next step, reduces friction, and the learner performs beautifully while using it. Does that count as successful teaching? How would you know whether the learner can now do it without the tool?
- Cognitive Load Theory distinguishes intrinsic, extraneous, and germane load. If you were designing an AI assistant, which type of load would you deliberately try to reduce, and which would you be careful NOT to remove?
- If a learner knows they can offload memory and reasoning to an AI, when is that a smart strategy and when is it a shortcut that quietly prevents learning? What determines the difference?
- Cognitivism assumes knowledge can be broken into components and tracked over time. What might get lost when we reduce a learner's understanding to a set of traceable knowledge components?

Introduction

Cognitive psychology is the learning-theory tradition that treats learning as a change in internal mental representations — concepts, schemas and procedures held in memory — rather than as a change in observable behavior. Its information-processing vocabulary (attention, encoding, retrieval, bounded working memory) supplied both the diagnostic language for learning difficulty and the architecture behind Intelligent Tutoring and Knowledge Tracing: systems that infer a learner's internal state and adapt to it. It remains the reference frame for Metacognition, Desirable Difficulties and Self-Regulated Learning across this knowledge base.

Su et al. (2026) reconstructed images from learners' EEG during science videos and found representation fidelity tracked test performance (regression coefficient 0.8481, $R^2 = 0.79$) — direct evidence that a measure of internal representation can index encoding

Core ideas

- **Learning is a change in internal mental representations.** Cognitivism holds that learning involves the acquisition, storage, and reorganization of knowledge in memory — concepts, schemas, and procedures — rather than just a change in observable response. What a learner *knows and can retrieve* matters, not just what they do.
- **The information-processing (computer) metaphor.** The mind is treated as an information-processing system with capacities and bottlenecks — measurement of latent ability, working-memory limits, encoding and retrieval — which is precisely the model that made AI tutoring (a computer program that models and adapts to learner cognition) a natural fit.
- **Attention and memory are bounded.** Working memory has limited capacity; durable learning requires encoding into long-term memory through rehearsal, elaboration, and retrieval practice. This connects cognitivism to research on Cognitive Offloading (delegating memory/processing to external tools) and to the "performance–learning gap" when AI bypasses retrieval and practice.
- **Metacognition regulates cognition.** Metacognition — monitoring and controlling one's own thinking — is a distinctly cognitivist construct, and it explains why learners' calibration of when to rely on AI matters for learning (see Cognitive Offloading and Self-Regulated Learning).
- **Knowledge is decomposable and traceable.** Cognitivist AIED assumes learner knowledge can be represented as components and tracked over time — the foundation of Knowledge Tracing, Cognitive Diagnosis, and Item Response Theory. Traceability is also a scoring rule. Four Knowledge Tracing update rules run over the same ASSISTments event sequences: crediting any assisted completion declared 93.9% of student-skill pairs mastered, against 72.8% when assisted rows read as failed first attempts. Pairs the lenient rule declared early went on to 0.709 unaided accuracy, against 0.857 where the rules agreed (Srivastava, 2026). The model tracks only what the evidence rule lets it count.

Cognitivism and AI in education

The cognitivist lineage of AIED

Cognitivism is arguably the theory most responsible for AI in education existing at all. The early cognitive tutors (e.g., Anderson's ACT-R-based tutors) embodied the assumption that learning could be modeled as production rules and that a system could trace which rules a learner had mastered. This produced the canonical architecture that still defines the field: a domain model, a student model that tracks the learner's knowledge state, and a pedagogical model that adapts instruction — all cognitivist in origin. Modern Knowledge Tracing (Bayesian, deep-learning, and IRT-based) and Cognitive Diagnosis continue this tradition. The same assumption underwrites Intelligent Tutoring, Adaptive Learning, and Personalized Learning, which are grouped in the knowledge base under the Learner Modeling and Adaptive Instruction umbrella.

Cognitive load and the design of instruction

Cognitive Load Theory (CLT) is the most widely applied cognitivist framework in instructional design: it distinguishes intrinsic load (task complexity), extraneous load (presentation friction), and germane load (schema-building effort). Well-designed AI should reduce extraneous load while preserving germane processing; poorly integrated AI reduces all three, leaving completed tasks with empty learning. CLT's working-memory framing is also central to debates about Cognitive Offloading — whether AI reduces harmful extraneous load or short-circuits the germane processing that produces learning.

Load tracked how effort was organized, not how much was spent: among 67 pre-service teachers designing lesson plans with GenAI, the higher-quality group did not differ on reported effort (2.85 vs 3.26) yet reported lower mental demand (3.09 vs 4.03) and frustration (2.12 vs 3.82) (Fang et al. (2026)).

Mayer's Cognitive Theory of Multimedia Learning (CTML) applies the same working-memory assumptions to the materials themselves, and its prescriptions are unusually concrete: learners do better from words and pictures together than from words alone, when extraneous material is excluded, when a lesson is segmented and user-paced rather than presented as one continuous unit, when corresponding words and pictures appear near and at the same time, and when narration is conversational and in a friendly human voice rather than formal or machine-generated.

Cognitivism vs. behaviorism and constructivism

- **vs. Behaviorism:** Behaviorism explains learning as observable behavioral change through reinforcement and drill; cognitivism insists on internal representations and traces mental states. AI practice often shows a "constructivism in name, behaviorism in practice" gap, but cognitivist designs (student modeling, knowledge tracing) are distinct from pure behaviorist drill-and-feedback because they *represent and adapt to the learner's inferred knowledge* rather than merely reinforcing responses.
- **vs. constructivism:** Constructivism holds that Learners actively construct meaning through experience; cognitivism emphasizes accurate encoding of (often pre-structured) knowledge and skill. AIED's cognitivist lineage (structured domains, explicit knowledge components) is sometimes critiqued as too behaviorist or too transmission-oriented by constructivists, while cognitivism counters that representing and tracing knowledge is what enables genuinely adaptive instruction.
- **vs. the learning sciences:** Cognitivism supplies the mechanisms that field designs with — working memory, encoding, retrieval, decomposable knowledge components — but is not itself design-oriented. It explains how learning happens; the learning sciences ask how to build environments in which it happens and hold those designs to empirical test.

The AI-era tension: cognitivism's boundary is under pressure

Generative AI both extends and challenges cognitivism. It extends it by making knowledge representations more powerful (LLMs as knowledge engines that can be traced via Knowledge Tracing and adapted via Learner Modeling and Adaptive Instruction). It challenges it by complicating where cognition "is": when AI performs reasoning, memory, and even metacognitive-like functions, the cognitivist assumption that learning

is internal processing in the individual mind is unsettled — as Distributed Cognition, co-regulation, and post-human framings argue cognition can be distributed across human and artificial systems. Yet the cognitivist question remains the field's central one: *does the learner internalize the knowledge, or does the tool hold it?* This is the cognitive-offloading and performance–learning gap question in its purest form.

Implications for design and research

1. **Design for internalization, not just performance.** Cognitivist AIED should be evaluated on whether the learner can retrieve and apply knowledge *without* the tool — not on assisted performance. This is the performance–learning gap and the rationale for measuring unassisted transfer.
2. **Represent the learner, don't just respond.** Attach structured Learner Modeling and Adaptive Instruction and Knowledge Tracing to AI dialogue so the system adapts to inferred knowledge rather than responding fluently but blindly.(EduClaw-Bench: A Long-Horizon Benchmark for Pedagogical LLM Agents with Simulated Learners)
3. **Respect working-memory limits.** Apply Cognitive Load Theory to AI UX: reduce extraneous load (friction, overloaded interfaces) while preserving germane processing (productive struggle, retrieval practice) rather than minimizing all cognitive demand.
4. **Calibrate metacognition.** Because Metacognition governs when learners choose to offload, teaching calibration (knowing what one can actually do unaided) is a cognitivist answer to over-reliance (see Cognitive Offloading).

Common Misconceptions

- **"Mental representations are unobservable, so cognitive claims about learning are assumptions."** Reconstructing images from learners' **EEG** during science videos found **representation fidelity tracked test performance** (regression coefficient **0.8481, R^2 = 0.79**). The cognitivist premise of internal representation is measurable, and the measurement predicted the outcome.
- **"A high R^2 means the representation explains the learning."** R^2 = 0.79 is a strong association between fidelity and performance on the same material. It does not establish that raising fidelity raises performance, which is the intervention claim.
- **"Knowledge components are a convenient modelling fiction."** Decomposability is what makes Knowledge Tracing and Cognitive Diagnosis possible, and the methods work to the degree that the assumption holds. Treating it as a fiction discards the reason the methods produce usable estimates — while treating it as fact overstates what a fitted model tells you about a mind.

Sociocultural Learning

> **Sociocultural learning** — the family of theories, rooted in Vygotsky, that holds learning and development arise through social participation and are mediated by cultural tools, language, and interaction with more knowledgeable others. Cognition is distributed across people, artifacts, and environments rather than residing solely in individuals. In AI in education, sociocultural theory frames how generative AI functions as a new kind of *mediational agent* — a tool that both mediates activity and generates contingent contributions to interaction — and frames the design of Scaffolding, the Zone of Proximal Development (ZPD), apprenticeship, and communities of practice. See Generative AI as a Mediational Agent: Rethinking Learning in Sociocultural Theory.

Questions to Consider

- Vygotsky's Zone of Proximal Development is the gap between what you can do alone and what you can do with help. Recall a time a well-timed hint let you accomplish something you couldn't alone — what made that help effective, and when might it have given too much away?
- The page claims human thinking is 'mediated' by cultural tools like language and writing that reorganize how we reason. If that's true, how should we think about an AI chatbot as a new kind of thinking tool — and how might it change what 'knowing' means?
- Sociocultural theory says cognition is distributed across people, artifacts, and environments rather than inside individual heads. Does that match your experience of how you actually get things done, and what would it mean for designing learning if it's right?
- If learning happens first between people and only later within the individual, what are the risks of an AI tutor that lets a student interact mostly with a machine rather than with peers or a more knowledgeable human?
- How would you decide how much support an AI tutor should give so that a learner advances without the answer simply being handed over?

Introduction

The concept

Sociocultural theory (Vygotsky, 1978; Luria; Leontiev) holds that higher mental functions develop through participation in culturally organized activity. Unlike accounts that locate learning solely in the individual's information processing, the sociocultural view emphasizes that:

- **Mediation is fundamental.** Humans think with and through cultural tools — language, writing, diagrams, technologies — which reorganize how they reason, remember, and solve problems (Wertsch, 1991). These tools do not merely transmit information; they reshape cognition and participation.
- **Learning is social.** Higher mental functions appear first between people (intersubjectively, in interaction) and only later within the individual. Learning arises through participation with

teachers, peers, and communities — in processes like Scaffolding, apprenticeship, and movement through the ZPD.

- **Cognition is distributed.** Cognitive work is spread across people, artifacts, and environments (Hutchins; Clark & Chalmers; Pea), rather than contained in the individual mind. Distributed cognition, situated learning, and communities of practice extend the sociocultural strand.

The Zone of Proximal Development (ZPD)

The ZPD (Vygotsky) is the sociocultural concept most widely applied in AI tutoring: the space between what a learner can do alone and what they can do with assistance. Learning happens most effectively when instruction targets this zone — challenging enough to push development, supported enough to make progress. It is the theoretical foundation of Scaffolding: temporary, adjustable support withdrawn as competence grows. In AI in education, ZPD frames the central design question of how much support an AI tutor should provide so learning advances without being given away — see The Evidence Base on AI in K-12: A 2026 Review.

Machine-made help can land inside that zone. In a randomized study of 274 adult learners across four mathematics subjects, ChatGPT-generated worked-solution hints produced a 17.00% pre-to-post gain against 1.85% with no hints, while human tutor-authored hints produced 11.62%; the two help conditions were not statistically separable (Pardos and Bhandari, 2024). The error rate qualifies the equivalence: 32% of the generated hints failed quality checks until self-consistency prompting cut that to near zero in the three algebra subjects and 13% in statistics. A more knowledgeable other that is wrong one time in three is still a mediational agent, which is why the machine's contribution has to be checked before a learner builds on it.

Sociocultural learning in AI education

Sociocultural theory shapes AIED research in several distinct ways:

- **AI as a mediational agent.** Generative AI complicates the sociocultural distinction between mediational means and social interaction: it both mediates activity *and* generates context-sensitive, contingent contributions that shape interaction, without possessing intentionality, social membership, or accountability. Warschauer, Tate, and Ritchie (2026) propose the *mediational agent* as a hybrid category, and derive human-first habits of participation (primacy of human cognition, purposeful engagement, supervisory agency, epistemic vigilance, reflective self-regulation) to preserve learner agency.(Generative AI as a Mediational Agent: Rethinking Learning in Sociocultural Theory)
- **A stage-sensitive account of AI's regulatory role.** A developmental framework of human–AI co-regulation gives AI four roles — scaffold, metacognitive support, external memory, and decision partner — and places them by stage: structured external regulation in early childhood, a metacognitive partner in middle childhood and adolescence, and a collaborator on complex cognition in adulthood.
- **ZPD-calibrated scaffolding.** AI tutors should dynamically calibrate help to sit within each learner's zone. The Evidence Base on AI in K-12: A 2026 Review shows how tutors tuned to a learner's level outperform generic assistance; Adaptive Learning and ProPACT: A Proactive AI-

Driven Adaptive Collaborative Tutor for Pair Programming operationalize ZPD by adjusting difficulty and hints; and principled frameworks like A principled way to think about AI in education: guidance for educators and policy makers on action based on goals, models of human learning, and use of technologies argue support should be withdrawn as competence grows.

- **The signal for leaving the zone is aim, not depth.** A tutor that escalates and fades per decision point conceded 65.0% of the time after a turn about a *different* decision, twice the rate for turns aimed at the decision under support, and depth of reply did not order the outcomes (Hou et al. (2026)). Withdrawal assumes a learner who answers: take-up fell from 37.0% after the first ask to 21.8% after the third, so a hush is not evidence of readiness.
- **A fourth zone: what the model knows.** Tsim and Gutoreva (2025) extend Vygotsky's diagram rather than the tutoring loop, adding a *known to GenAI* zone to the ZPD and reading off four sub-zones that classify what a task should be assigned to: Substitute (no task-specific knowledge, so the model's general competence carries it), Aid (partial knowledge, augmented), Complement (enough knowledge to supervise the model's output), and Non-negotiable (enough to do it unaided, so delegation adds little). Scaffolding is expressed as task assignment rather than hint delivery, and a metacognitive loop of real-time evaluation, reflection and learning is what moves a task between sub-zones over time.
- **Apprenticeship and community.** Sociocultural ideas underpin cognitive apprenticeship, modeling, coaching, and fading; communities of practice frame learning as movement toward fuller participation in a community's practices.
- **Cultural and institutional context.** The constructivism-adjacent sociocultural strand stresses that the cultural dimension shapes what counts as knowing, who is an authority, and what effort means — see the Sydney PreK-12 rapid review's learners–contexts–cultures framing.
- **Validating talk measures requires the youth whose talk is measured.** Re-contextualizing talk-move definitions with four focal students raised Large Language Models (LLMs) classification F1 by +0.104 for Claim and +0.23 for Question, and students' own interpretations diverged from adult and model framings — a structural limit of text-based classification, not a data-size problem (Santos-Deonizio et al. (2026)).

Connection to cognitive load and metacognition

The sociocultural strand is tightly coupled to Cognitive Load Theory (support should manage load without eliminating productive effort) and to Metacognition (learners in the zone are actively monitoring and regulating their understanding). The Evidence Base on AI in K-12: A 2026 Review synthesizes K-12 evidence that AI tools work best when they keep learners in the ZPD rather than answering for them, and Human-in-the-Loop research addresses how human and AI support jointly define the learner's zone.

- **Generative AI as a mediational agent (2026):** Drawing on Vygotskian mediation, a theory paper proposes reframing generative AI not merely as a tool/mediational means but as a *mediational agent* that actively participates in learning activity, blurring the tool-vs-social-interaction boundary central to sociocultural theory (Generative AI as a Mediational Agent: Rethinking Learning in Sociocultural Theory). This positions generative models as co-participants rather than passive

instruments, with implications for how mediation, Learner Agency, and the learner–AI relationship are theorized in the learning sciences.

Common Misconceptions

“Sociocultural theory is about social factors in learning as a supplement to individual cognition.” The stronger claim is that cognition is **distributed across people, artifacts and environments** rather than residing inside individual heads. On that view an AI is not an external helper added to a learner’s cognition; it is a component of the system the cognition runs in, which changes what should be measured.

“If cognition is distributed, individual assessment is measuring the wrong thing.” It changes the interpretation rather than removing the measurement. What the assessment captures depends on what is present in the system at the time, which is why assisted and unassisted performance diverge — they are measurements of different configurations.

“Adding a tool to a group changes only the group’s efficiency.” It changes the division of labor, which is the unit the theory analyses. A group that routes most of its questions to an agent has redistributed the cognitive work even when the output is unchanged.

“Distributed cognition implies the individual does not matter.” It implies the individual’s contribution cannot be read off individual performance alone; the unit of analysis is the activity system, not the person in isolation.

Distributed Cognition

> **Distributed Cognition** — the theoretical perspective that cognition is not confined to an individual mind but is distributed across people, tools, artifacts, and environments. In AI-in-education research, this framework has become central for understanding human–AI collaboration: rather than viewing AI as a neutral tool that supports an otherwise self-contained learner, distributed cognition treats thinking as emerging from the interplay between learners, AI systems, peers, and their shared context. It reframes questions of Learner Agency, responsibility, and learning outcomes in terms of how cognitive work is apportioned across a human–AI system.

Questions to Consider

- Distributed cognition says thinking isn't confined to a single mind but is spread across people, tools, and environments. When you use a calculator, a notes app, or an AI assistant, where does the 'thinking' actually happen?
- If cognition is distributed across a human and an AI, who is responsible when the result is wrong — and who is accountable for learning?
- One framework distinguishes AI's 'functional agency' (it can influence outcomes) from 'moral responsibility' (which remains human). Does that distinction hold up in practice, or does responsibility blur when humans can't understand what the system did?
- Human-AI systems that distribute reasoning most efficiently tend to produce the highest task performance but the least self-regulated learning. Why would making a system 'smarter' at the group level make the individual learner weaker?
- The 'Cognitive Commons' argument holds that distributed mastery depends on internalized expertise — you can't effectively oversee an AI system you don't deeply understand. How does that challenge the idea that AI lets us skip the hard work of learning?

Introduction

This is a learning-theory concept within the knowledge base's Learning Theories strand, closely related to Embodied Learning, Situated Learning, and Cognitive Offloading. Distributed cognition (DCog), originating in the work of Edwin Hutchins and colleagues, describes how cognitive processes such as memory, reasoning, and Problem Solving are spread across multiple agents and material systems rather than residing in a single head. In AI education this matters because AI systems increasingly function as genuine cognitive partners that carry part of the thinking load, raising the question of *where* learning actually happens and *who* is responsible.

How AI shifts the distribution of cognition

Generative and interactive AI systems redistribute cognitive work in ways earlier tools did not. The knowledge base documents several dimensions of this shift:

- **AI as a cognitive partner and co-regulator.** AI can act as a scaffold, metacognitive support, external memory system, and decision partner in the co-AI Regulation in Education of thinking and learning.(Artificial intelligence as a cognitive partner: a developmental framework for human-AI co-regulation in learning) This positions cognition as co-regulated between learner and system rather than individually managed.
- **Volume of AI use does not reveal which form of distributed work is happening:** Poquet et al. (2026) found the volume-based profiles of 97 learners differed in prior knowledge and authorship but not in active-role or comprehension-level prompting, so shared activity and division of labor can accompany the same amount of use.
- **Agency and responsibility redistribution.** Frameworks such as **ensemble cognition** reconceptualize thinking as emerging from dynamic human–AI interaction, distinguishing AI's *functional agency* (its capacity to influence outcomes without consciousness) from *moral responsibility* (which remains human).(Towards a philosophy of ensemble cognition: Reconceptualising agency and mind in AI-mediated educational environments) Distributed cognition thus reframes who is accountable for learning.
- **The efficiency–regulation tension.** Empirical work shows a trade-off: human–AI systems that distribute reasoning most efficiently (e.g., via delegated reasoning) achieve higher task performance but may reduce learners' self-regulatory engagement.(Unpacking Interaction Profiles and Strategies in Human-AI Collaborative Problem Solving: A Cognitive Distribution and Regulation Perspective) This is the empirical face of the Cognitive Offloading and Over-Reliance risks the knowledge base documents.
- **Mediation in collaboration.** AI can act as a *pedagogical mediator* that orchestrates interaction, epistemic sense-making, and regulatory processes in collaborative learning, redistributing agency, authority, and responsibility across human and non-human actors.(Beyond Automation: AI as a Pedagogical Mediator in Collaborative Learning)
- **Access configuration distributes cognition within the group.** Xu et al. (2026) show that *how* a team shares GenAI determines the distribution of cognition: synchronous work on a single shared interface sustains a common cognitive model (collective prompts, shared external memory), whereas asynchronous private use fragments it, with outputs selectively re-labeled before sharing. GenAI thereby functions as both a distributed cognitive participant and an interactive collaborative space whose permeability must be designed (shared context flows in, private insights do not auto-flow back).
- **Teachers too experience AI-dominant versus complementary distribution.** The same efficiency–regulation logic applies to the teacher side of lesson design: Choi et al. (2026) found that novice teachers delegate a large share of instructional-design cognitive load to the AI system (an AI-dominant distribution, largely accepting responses), whereas experienced, AI-proficient teachers reach a complementary distribution in which pedagogical expertise and AI's

computational support mutually reinforce. Because GenAI generates and co-constructs rather than merely stores information, they frame this as *participatory shared cognition*, not mere tool use.

- **Interaction types, not outcomes, as the unit.** Willcox, Lane and Arikan (2026) built the **Cognitive Distribution Framework** from 53 logs of self-directed ChatGPT use: five interaction types (extension, outsourcing, alignment, transformation, decoupling) and four user roles, so the same student can offload in one exchange and co-think in the next.
- **Transactive memory gives the distribution a measured mechanism.** Among 891 college students in the United States and Türkiye, neither self-appraised thinking ability nor confidence in the AI partnership predicted critical thinking directly. Both worked through accumulated GenAI experience, which mattered only via specialization and coordination of labor (b = 0.636) and reflective transformation of output (b = 0.367) (Akgun & Toker, 2026). Those two mediators then predicted critical thinking (b = 0.230 and 0.175) with no direct path left, so what a human-AI system thinks with is the arrangement of the work, not the amount of use.

Distributed cognition and related perspectives

The knowledge base treats distributed cognition alongside its neighboring theoretical traditions, which overlap but are not identical:

- **Situated learning / situated cognition** emphasizes that cognition and learning are inseparable from the authentic context and communities of practice in which they occur — a complement to DCog's focus on cognitive *distribution* across systems.
- **Embodied cognition** stresses the role of the body and sensorimotor interaction, arguing that thinking is grounded in bodily engagement rather than abstract symbol manipulation.
- **Cognitive Offloading** is the practical mechanism by which cognitive work is handed off to external systems (including AI), and is the risk-laden counterpart to DCog's descriptive account.
- **Extended cognition / the extended mind thesis** (used in posthumanist work) holds that external artifacts can be *constitutive* parts of a cognitive system, not merely instruments — a stronger claim that AI is part of the learner's mind itself.(Pedagogical Symbiosis: conceptualizing the Post-Human Learner in the age of cognitive AI)

Whose cognition? The unit-of-analysis problem

Schlauch (2026) pushes that unit-of-analysis question harder than most work in this tradition. His claim is that literacy is not an individual possession but something enacted with materials and machines, which makes the individual learner the wrong unit of analysis. A competence framework centered on the person therefore cannot register infrastructural or nonhuman contributions, so the field keeps naming distribution and then resolving it back onto the learner. The equity edge is his difficulty argument: reflexivity depends on lived experience and relations of power, so students whose language or writing practices sit furthest from the encoded norm carry the largest cost. The argument is theoretical and reports no dataset, and its design orientations remain untested proposals.

Why it matters for AI design and evaluation

Distributed cognition provides both a design lens and an evaluation lens. For design, it asks how to apportion cognitive work between learners and AI to preserve (not erode) the human learner's agency, Metacognition, and self-regulation. For evaluation, it reframes success metrics: instead of asking only "did performance improve?", DCog asks whether the distribution of cognition supports durable learning, epistemic agency, and educational justice — a perspective that connects to the knowledge base's AI Ed Evaluation and Learning Theories concerns.

Fowlin et al. (2026) operationalize that apportionment as a two-phase sequence: build core competencies without AI first, then introduce AI as a cognitive partner whose suggestions students critically evaluate, to prevent automation-related deskilling (Fowlin et al. (2026)).

Internalized vs. distributed mastery. The Cognitive Commons framework (Lovett 2026) distinguishes Internalized Mastery (deep domain knowledge in individual minds) from Distributed Mastery (orchestrating human–AI systems) and argues the latter depends on the former via a "Validation Tether": effective oversight of distributed/AI systems presupposes the internalized expertise those systems may undermine. This sharpens the DCog design question — the distribution of cognition must not come at the cost of the expertise that validates it.

Common Misconceptions

- **"A shared document means shared cognition."** Volume-based profiles of **97 learners** differed in **prior knowledge and authorship** but **not in active-role or comprehension-level prompting**. Participation volume measured exposure, not the distribution of cognitive work — so usage analytics of a collaborative tool say little about who was thinking.
- **"Everyone offloads to AI equally."** Novice teachers **delegate a large share of instructional-design cognitive load to the AI system**, arriving at an **AI-dominant distribution** in which they largely accept responses, whereas experienced and AI-knowledgeable teachers distribute differently. Expertise shows up in where the load is placed, not only in how much AI is used.
- **"More AI involvement means more support."** An AI-dominant distribution is the pattern to watch for, because the human's share of the cognitive work shrinks while the output volume rises. The system can look more capable precisely as the user is doing less.

Situated Learning

> **Situated Learning** — the theory, rooted in the early-1990s work of Lave and Wenger (1991), that learning is not an isolated, decontextualized act but occurs through participation in authentic activities, contexts, and cultures. Knowledge is co-constructed by learners and peers within communities of practice, and novices learn through legitimate peripheral participation — absorbing the culture, language, and practices of expert members as they move from the periphery to the center of a community. Emphasis falls on learning by doing in real-world situations, where Assessment emerges from the task itself rather than being separated from it.

Questions to Consider

- Think of something you genuinely know how to do well — a skill, a trade, a craft. Did you learn it mostly from abstract instruction or from participating in a real community that did that thing? What does that suggest about where knowledge actually lives?
- Lave and Wenger describe novices learning through ‘legitimate peripheral participation’ — starting at the edge of a community of practice and moving inward. Where have you watched (or been) such a newcomer, and what let them move from the periphery to the center?
- If knowledge is ‘situated’ in authentic contexts, what does that imply for the traditional classroom, which deliberately separates learning from real-world situations — and for AI tools designed to deliver decontextualized content?
- The page treats situated learning as a design lens for AI. How might an adaptive system or simulation ground learning in authentic practice rather than pulling it out of context?
- What obstacles does the research say stand in the way of situating AI-driven learning in real contexts, and which of those have you seen in your own institution?

Introduction

Situated learning is one of the activity-and-context theories within the knowledge base’s Learning Theories strand. It takes up Vygotskian themes of social construction but adds a strong emphasis on the intimate integration of “doing” and “learning” and on the importance of communities of practice. As an educational stance it confronts traditional, standardized schooling by foregrounding the learner’s sociocultural context as a key element for acquiring skills and appropriating knowledge relevant to their reality.

In the AI-in-education literature, situated learning matters because it provides a design lens for AI: adaptive systems, intelligent tutoring in authentic scenarios, and immersive simulations can ground AI-driven education in real-world contexts, while situated learning in turn offers AI a meaningful anchor in authentic practice and complexity. The two are widely treated as complementary, with human guidance remaining essential for ethical grounding. - **Contextualizing the material itself is a situated-learning move.** DagFlow-AI generates a statistics dataset built around a student’s own stated interest — one case study used a student’s concern about climate change and health — while holding the learning objectives and skill level fixed (Arthur et al., 2026). Matching the *data* to the learner, rather than matching the explanation, treats the

context of practice as the thing that needs situating. The authors concede the limit: synthetic data cannot teach data collection, measurement or study design, so the context is real to the learner but not to the world.

Situated learning as a design lens for AI

The knowledge base's research treats situated learning not merely as an abstract theory but as a concrete design and evaluation framework for AI in education:

- **Opportunities and obstacles.** A PRISMA systematic review of 60 articles (three decades) finds that AI can augment situated learning — through adaptive systems tailored to students' evolving needs, intelligent tutoring situated in authentic scenarios, automation of administrative tasks, and data-driven teacher support — while the main obstacles are the traditional school's one-way passive learning, an over-emphasis on predefined outcomes, and teachers' limited contextual knowledge. Human guidance remains essential for ethical grounding.(Reshaping education in the era of artificial intelligence: insights from Situated Learning related literature)
- **AI as a catalyst connecting education to reality.** AI can act as a *catalyst* for situated learning by connecting education with reality and authentic contexts, enabling learning grounded in real-world scenarios.(Connecting Education with Reality: AI as a Catalyst for Situated Learning)
- **Mediational artifacts in authentic inquiry.** In science learning, AI tools (virtual labs, simulations, intelligent tutoring) function as "mediational artifacts" that extend situated learning by enabling digital communities of practice and boundary-crossing between school, real-world, and interdisciplinary contexts — transforming students from "knowledge learners" into "scientific practitioners."(Artificial Intelligence in Science Learning within the Framework of Situated Learning Theory: A Qualitative Investigation of Teachers' Perspectives)
- **Situated curriculum devices.** AI literacy can be developed through *Episodes of Situated Learning* — active teaching instruments (anticipate, produce, reflect) that build AI competencies through real-world Problem Solving rather than abstract instruction.(Towards AI literacy: A proposal of a framework based on the Episodes of Situated Learning)
- **Situated evaluation in design-based learning.** Yaşar et al. (2026) grounded their study in situated-learning theory and iterative design Pedagogies and Teaching Strategies, evaluating 80 student design posters across instructor, peer-reviewer, and grant-reviewer roles. Role-aware prompting produced qualitatively different evaluative feedback — instructors encouraging and process-oriented, peers supportive and conversational, grant reviewers formal and outcomes-oriented — differences that were epistemic, not merely stylistic, foregrounding different aspects of design practice. This shows how situated, role-specific evaluation can be emulated by an LLM when scaffolded with a semantically precise rubric, and how assessment in design-based learning emerges from the authentic task and its roles rather than being separated from them.
- **Situated AI ethics.** Ethical reasoning about AI is itself best treated as *situated* — grounded in cultural-historical and ecological context rather than abstract principles.(Situated AI ethics: a cultural-historical and ecological framework for education)

Situated learning connects closely to Embodied Learning (both stress the grounding of cognition in context and action), Distributed Cognition (learning distributed across people, tools, and contexts), Experiential Learning, and Constructivism theory. In AI education it grounds the critique of decontextualized,

disembodied learning: AI design that keeps learners anchored in authentic practice preserves the situatedness that durable learning requires.

- **Scenarios and reusable assets as infrastructure.** AI Cosmos (2026) operationalizes situated learning as a scenario — objective, role-specialized agents, queryable knowledge and a stateful workbench — plus an asset memory that preserves process records and experience traces with their provenance so later scenarios can retrieve prior practice. Two preregistered three-arm randomized trials found a 7.0-point learning-gain advantage over a vanilla assistant in legal reasoning (d = 0.56) and a larger share reaching criterion mastery in competitive programming (68% against 45%), while prompting the same model to act as a teacher produced no detectable benefit. It is a rare test of the claim that situation and workspace carry more of the learning than conversational explanation does.

Common Misconceptions

- **"Situated learning means adding a realistic scenario to an abstract lesson."** The theory's claim is stronger than context-dressing: learning is constituted by participation in a community of practice, and what is learned is what that participation affords. A worked example with a workplace framing attached still teaches the example, not the practice.
- **"Authenticity is a property of the task."** Authenticity is a relation between the activity and a real community's legitimate work. A task can be elaborate and still be school-shaped — assessed by a teacher, for a grade, with no consequence in the world it claims to represent.
- **"Assessment emerging from the task means no assessment."** It means the criterion is the community's, not the classroom's: whether the work is acceptable to people who do the work. That is a different and usually stricter standard than a rubric.
- **"Apprenticeship requires a physical setting."** The mechanism is legitimate peripheral participation — moving from the edge of a practice toward its center with real responsibility. Online and simulated settings can support it or can simulate the periphery without ever granting participation, and the difference is whether the learner's contribution is actually used.

Embodied Learning

> **Embodied learning** — the pedagogical principle that learning is grounded in bodily experience, physical interaction, and the sensory-motor context of the learner. Embodied approaches hold that cognition is not purely abstract but shaped by the body and its interaction with the environment. In AI in education, embodiment is realized through educational robots and social robots, whose physical presence grounds abstract concepts (such as program logic or social skills) in observable, manipulable behavior.

Questions to Consider

- We often think of learning as something that happens 'in the head,' with the body just carrying the brain around. What if learning is actually grounded in bodily experience and interaction with the environment? What's one subject you learned that seemed to require your body — and could it have been learned purely abstractly?
- Embodied approaches claim a physical, manipulable agent helps learners connect abstract ideas to concrete outcomes — seeing a program make a robot move, for instance. When have you noticed that doing something physical made an abstract concept finally 'click'?
- Some researchers treat gesture as evidence of understanding — tracking students' hand movements alongside their speech to assess conceptual grasp. If a student's hands 'know' the concept before their words do, what might that imply about how we should assess learning?
- An emerging critique challenges 'disembodied' AI that operates on abstract symbols, arguing AI should be designed around embodied intelligence to sustain learners' thinking rather than outsourcing it. Do you think an AI that has never had a body can fully support embodied learning?

Introduction

Embodied learning is closely related to Active Learning, Experiential Learning, and situated/Constructivism theories. The key claim is that a physical, manipulable agent helps learners connect abstract ideas to concrete outcomes — a program that makes a robot move, or a role-play with a physical robot — in ways that pure screen-based interaction may not. Robotics is the clearest embodiment of AI in education, giving learners something to see, touch, and observe.

How embodied learning appears in the knowledge base's research

- **Grounded programming:** RoboBlockly Studio grounds block programming in embodied robot execution, creating a tight loop of authoring, running, observing, and revising so learners see their code become behavior.
- **Social-robotic interaction:** Social robots used for storytelling (MotiBo, RoboBuddy), role-play (REMind), and sign language (Pepper) provide embodied social interaction that supports relational and emotional learning.

- **Embodiment features are not what drives outcomes.** A meta-analysis of 11 RALL studies (N = 595, g = 0.83, I^2 = 84.4%) found robot morphology, modality, autonomy, and social role did not moderate L2 learning; group-based formats beat one-on-one, so the robot's position, not its embodiment, carried the effect (Wang et al. (2026)).
- **Embodiment and creative writing:** Research on robot-LLM integration in creative writing examines how embodiment affects learners' interaction and outcomes.
- **Human-robot interaction:** HRI research (trust, agency) examines how physical embodiment shapes trust, engagement, and autonomy.
- **Gesture as evidence of understanding:** Morphew et al. integrate computer-vision gesture tracking with Large Language Models (LLMs) analysis of speech to show that engineering students' conceptual understanding of statistics is expressed through both speech and gesture. High-confidence explanatory gestures cluster around specific concepts (especially the mean), and close gesture–speech coupling signals coherent conceptual talk while divergence marks developing ideas — positioning embodied action as evidence in assessment via multimodal learning analytics, not only as a learning mechanism.
- **A language-only facilitator pulls inquiry toward what can be said.** In a Master's fluid-statics laboratory, students built the buoyancy model by hand before a Gemini-based facilitator joined to apply it to a new phenomenon. Across three pairs the AI held the ISLE sequence, but pressed to "just tell us" it produced mass values nobody had measured, and one remote participant completed a physically correct cycle that was clean but disembodied (Tufino & Damiani, 2026). The design lesson is sequence rather than substitution: build the model in the body first, then let the language model work on applying it.

Embodied intelligence and the critique of disembodied AI

A second, more theoretical strand of the knowledge base's embodiment research concerns the role of the *body* in AI-mediated learning — not through physical robots, but through the question of whether AI systems themselves are (or can be) embodied. This work challenges the dominance of symbolic, disembodied AI models built on abstract information processing:

- **Embodied AI as a design principle.** The **E3-HOT framework** argues that to sustain learners' cognitive agency and higher-order thinking (rather than encouraging cognitive outsourcing), AI should be designed around *embodied intelligence* — situational embedding, embodied participation, and cognitive creation — within a virtual–real integrated learning environment. (Fostering Sustainable Learning via Embodied Intelligence: The E3-HOT Framework for Higher-Order Thinking in the AI Era)
- **The limits of disembodied generative AI.** Post-cognitivist scholarship argues that current GenAI systems lack proprioception, multimodal agency, and embodied practice, and advocates an "embodied AI" grounded in situationality, emergence, and sensorimotor coupling, proposing a perceptual–affective choreography for human–AI interaction.("If You Can't Dance Your Program, You Can't Write It": Challenges and Implications for AI in Education)
- **Embodiment, situatedness, and social construction.** In science learning, AI tools function as "mediational artifacts" that enable digital communities of practice and boundary-crossing,

connecting embodied, authentic inquiry to real-world and interdisciplinary contexts.(Artificial Intelligence in Science Learning within the Framework of Situated Learning Theory: A Qualitative Investigation of Teachers' Perspectives) This ties embodiment to Situated Learning and Distributed Cognition.

Embodied learning connects to Robots in Education, Robots in Education, Robots in Education, Active Learning, Experiential Learning, Situated Learning, Distributed Cognition, Computational Thinking, and Social-Emotional Learning. - **Body tracking turns regulation into a measurable signal.** In a mixed-reality photosynthesis simulation where motion tags moved student agents across a projected model, an LLM pipeline labeled 470 segments of self-regulated behavior in 40 minutes of video, enacting dominating at 66.4% (Fonteles et al., 2026). - **AI mostly watches the body rather than joining it.** In a PRISMA review of 23 AI-for-embodied-learning studies, the 40 coded AI roles were dominated by sensing: analysis and evaluation 40.0% and recognition and detection 22.5%, against 35.0% for roles acting inside the activity (feedback and coaching 15.0%, interaction 12.5%, content creation 7.5%). Dropping the three Low-rated and four unappraisable papers cuts interaction to 6.7% and content creation to 3.3%, so the evidence that AI joins the embodied loop rests on the weakest papers (Kim and Han (2026)).

- **The most bodily literature measures the body least.** Of 32 outcome tags, cognitive outcomes took 43.8%, affective 34.4% and psychomotor 21.9%, an ordering that held among the 16 higher-rated papers (24.0% of 25 tags). The authors blame the difficulty of selecting psychomotor measures and a habit of prioritizing cognitive gains, not a weak effect on bodily skill. None of the reviewed systems was designed for learners acting together; the collaboration that appears is cooperation between teacher and AI (Kim and Han (2026)).

Common Misconceptions

- **"The body is what makes embodied learning work."** A meta-analysis of **11 RALL studies (N = 595, g = 0.83, I^2 = 84.4%)** found that **robot morphology, modality, autonomy and social role did not moderate** second-language learning outcomes. The embodiment features were not the active ingredient, and heterogeneity was high enough (I^2 = 84.4%) that the pooled effect describes a very mixed set of interventions.
- **"A large effect settles the mechanism."** g = 0.83 with 595 participants across 11 studies is a real signal and it does not identify what produced it. Since the design features did not moderate the effect, the plausible mechanism sits in the pedagogical activity rather than the hardware — which changes what to invest in.
- **"Embodiment cannot be measured, so it stays theoretical."** Body tracking can turn regulation into a **measurable signal**: in a mixed-reality photosynthesis simulation where motion tags moved student agents across a projected model, an LLM pipeline labeled **470 segments** of regulation behavior. The construct is operationalisable even where it is hard to define.

Community of Inquiry

> **Community of Inquiry (CoI)** is a framework for conceptualizing a meaningful educational experience as the dynamic interplay of **cognitive presence**, **social presence**, and **teaching presence**. Originating in computer-mediated and online learning research (Garrison, Anderson & Archer, 2000), it has become one of the most widely used models for designing, evaluating, and researching online and blended inquiry-based education. In the Generative AI era the framework is being reconceptualized: machine-produced discourse can mimic authentic presence, so presences must be understood as sociotechnical accomplishments of human–GenAI assemblages rather than purely human activity.

Questions to Consider

- In an online course, what tells you that meaningful learning is actually happening — and how would you know if it weren't?
- The Community of Inquiry framework names three presences: cognitive, social, and teaching. In your own online experiences, which presence most often goes missing — and what does that do to learning?
- If an AI chatbot writes fluent, empathetic-sounding replies in a discussion forum, is 'social presence' happening? Or is presence something only humans can genuinely create?
- Generative AI can produce explanations so coherent they feel obviously right — but coherence isn't the same as correctness. Where have you seen 'fluency mistaken for warrant,' and how would you guard against it in an inquiry course?
- This framework suggests presences are 'sociotechnical accomplishments' of human-and-AI working together rather than purely human activity. Does that reframe who you hold accountable when an online discussion goes shallow or goes well?

Introduction

The Community of Inquiry framework describes a worthwhile online learning experience as the product of three interacting presences: cognitive presence (learners constructing and confirming meaning through sustained reflection and discourse), social presence (participants projecting themselves socially and emotionally), and teaching presence (design, facilitation and direction of the process). Grounded in Constructivism and Deweyan traditions, it treats inquiry as social and iterative, and it now serves as a design and evaluation lens for AI-mediated courses — where a Pedagogical Agent may support one presence while quietly eroding another.

The three presences

- **Cognitive presence** — the extent to which learners construct and confirm meaning through sustained reflection and discourse, operationalized via the *practical inquiry* model (triggering event → exploration → integration → resolution).
- **Social presence** — the ability of participants to project themselves socially and emotionally, expressed through affective communication, open communication, and group cohesion.
- **Teaching presence** — the design, facilitation, and direction of cognitive and social processes to realize personally meaningful and educationally worthwhile outcomes, including design/organization, facilitating discourse, and direct instruction.

CoI is grounded in Constructivism and Deweyan pragmatic traditions: inquiry is social, iterative, and driven by a felt difficulty that motivates the search for resolution.

CoI as a framework for online teaching

CoI originated in, and remains most strongly associated with, Online Teaching and Learning. It provides a vocabulary for diagnosing *why* an online course works or fails: low engagement and isolation in asynchronous courses are usually failures of social and teaching presence, while surface discussion often reflects weak cognitive presence. This makes CoI a practical design lens for the very conditions the online medium creates — the removal of physical co-presence, the need for deliberate community-building, and the structuring of discussion that substitutes for face-to-face contact. In the Generative AI era, CoI is also where online instructors confront the hardest new questions: who is "present" when Large Language Models (LLMs) agents post, moderate, or respond, and how to keep the three presences meaningful when machine-generated discourse can mimic them. The knowledge base's online-teaching page therefore treats Community of Inquiry as the core framework for the social-presence and community-building strand of its recommended practice.

CoI under generative-AI pressure

GenAI destabilises the assumption that indicators of presence can be attributed primarily to human learners and instructors (see Ba, Gašević, Lim & Anderson). It can:

- **Inflate cognitive presence** — fluent machine-generated explanations accelerate sense-making but risk premature closure when coherence is mistaken for warrant.
- **Mimic social presence** — machine-produced utterances can resemble empathy and responsiveness with high linguistic credibility, complicating relational accountability.
- **Redistribute teaching presence** — design, facilitation, and direct instruction become distributed accomplishments, with instructors modeling how to interrogate generated outputs and detect hallucinated citations.
- **Intervene too eagerly** — in an online-discussion study, expert facilitators were consistently more cautious about intervening than LLM judges, which were excessively eager to facilitate; the best trained classifier still hit a low ceiling imposed by the available datasets (Tsirmpas, Korre and Pavlopoulos, 2026). Redistributed teaching presence therefore changes the intervention threshold,

and a model will interject where a person would have waited, which is the failure mode a discussion forum notices.

Empirical network evidence now sits under these claims: in a quasi-experiment where 63 Chinese undergraduates (33 with, 30 without a GPT-4o mini chatbot) annotated shared readings on CollaboRead across five weekly tasks. The epistemic network analysis showed the assisted class binding social presence to integration and resolution while the control class bound social presence to triggering and exploration (X-axis U = 25.00, p = 0.01, r = 1.00; Y-axis U = 13.00, p = 1.00, r = 0.04). Self-reported cognitive and emotional engagement was higher in the assisted class. The presences then separate inside the condition rather than between them: high-achieving groups initiated 1407 feedback requests across 2319 annotations (60.7%) against 737 across 2167 (34.0%) in the low-achieving group, which stayed in a self-referential loop and weakly leveraged the scaffold.(Pan et al., 2026)

Rather than a tool, a dialogic partner, or a speculative "fourth presence," GenAI is best understood as an **epistemic condition** — a pervasive influence that reconfigures how presences are enacted, interpreted, evidenced, and governed through both visible outputs and invisible training-data, algorithmic, and platform logics.

The framework's own authors supply a role taxonomy for that condition: Stenbom and Garrison (2026) place AI as Learning Design support, an independent learner resource, an instructor-support function via analytics, a community member, and a sustained dialogical partner, and propose shared Metacognition — self- and co-regulation — as what keeps learners auditing AI output.

Practical implications

- The relationship between GenAI involvement and inquiry quality is **conditional on human accountability**, not linear: strong presence can occur with high or low GenAI involvement when accountability is strong, and weak presence with either when accountability is weak.
- Assessment of inquiry should shift from polished final outputs to **process-sensitive evidence** — prompting and revision traces, disclosure and attribution practices, verification moves, and interaction logs. This aligns with the knowledge base's broader move toward authentic, process-revealing assessment and away from detection-based responses.
- Pedagogically, learners often need explicit training (e.g., simulation-based practice with scripted roles and GenAI decision points) to sustain authentic inquiry under GenAI conditions — and instructors should model how to interrogate generated outputs, which depends on building AI Literacy, critical appraisal, and calibrated trust.

Common Misconceptions

"Teaching presence is a human property." In the generative-AI era the framework is being reconceptualized because machine-produced discourse can mimic authentic presence, so the presences are better understood as sociotechnical accomplishments of human–GenAI assemblages rather than purely human activity. A course can report high teaching presence with the instructor largely absent and a model doing the discourse.

“Coherent AI explanation creates cognitive presence.” Coherence is not correctness, and it is precisely the property that makes reflective inquiry hard to sustain: a student who feels an explanation is obviously right has been given little occasion to resolve a triggering event. Cognitive presence requires the resolution of doubt, not the removal of it.

“Presence is distributed evenly across a cohort.” It separates *inside* the condition rather than between conditions. In a quasi-experiment with **63 Chinese undergraduates (33 with a GPT-4o mini chatbot, 30 without)** annotating shared readings across five weekly tasks, the presences diverged by group achievement: high-achieving groups initiated **1407 feedback requests across 2319 annotations (60.7%)** against **737 across 2167 (34.0%)** in low-achieving groups. Access to the same tool reproduced an existing gap in the social behavior the framework measures.

“Adding a chatbot to an online course adds a presence.” It changes the mix. The framework’s value under GenAI is that it makes the substitution visible: a presence satisfied by a model is a different configuration of the same construct, and the cohort data show the substitution paying off unevenly.

Connected FAQs

- How Should We Design and Facilitate Asynchronous Online Courses When AI Can Do the Work?

Self-Regulated Learning

> Self-regulated learning (SRL) describes learners as active participants who can shape and develop their cognitive and behavioral actions in a successful way. AI tools can either scaffold SRL development or inadvertently short-circuit it by removing the regulatory demands that build expertise.(Designing a mobile chatbot-based learning journaling system for intrinsic motivation and engagement)(The Evidence Base on AI in K-12: A 2026 Review) Longitudinal evidence sharpens the distinction: reflective use around an AI tool predicted critical thinking (β = 0.43) but not knowledge gain, and tool access on its own changed neither.(Generative AI and Learning Dynamics in Higher Education: A Longitudinal Empirical Study)

Questions to Consider

- SRL describes learners actively managing their learning through three phases: forethought (goal setting, planning, self-efficacy), performance (strategy, self-observation), and self-reflection (evaluation, adaptation). Before you read, which phase do you actually do well — and which do you skip even though you know better?
- The page's core tension: AI can scaffold self-regulation or short-circuit it by removing the regulatory demands that build expertise. How can a tool that makes a task easier also make you a weaker regulator of your own learning — and can you feel the difference in your own use?
- Students often show a 'production deficit': they possess self-regulation knowledge but fail to deploy it spontaneously — asking a chatbot to 'extract the main ideas' and skipping planning and monitoring entirely. Have you caught yourself doing the cognitive equivalent of this, even while knowing the better strategy?
- When support is present, your own judgment can drop out of the picture: in one trace-data study the available support, not the learner's metacognitive accuracy, was what determined the revision strategy chosen. If external help overrides your read on your own learning, which judgment would you deliberately keep in your own hands?
- Research found a 'miscalibration gap': students can *perceive* more learning with GenAI while retaining less — preferring AI over note-taking despite weaker retention. If you feel productive while using a tool, how would you ever discover that you're not actually learning more?
- Whether GenAI functions as a scaffold, shortcut, or partner depends more on the learner's regulatory capacity than on the tool itself. But the page also shows self-regulation buffers — yet does not cancel — the harm of deep cognitive offloading. What does that 'buffers but doesn't cancel' caveat mean for designing better AI tools?
- Set a goal before reading: pick one task you regularly use AI for, and decide in advance which of the three SRL phases (forethought, performance, reflection) you'll deliberately protect from being automated. What result will tell you it worked?

Introduction

SRL is the process whereby learners actively manage their own learning through three interrelated phases:

1. **Forethought:** Goal setting, strategic planning, Self-Efficacy beliefs
2. **Performance:** Strategy deployment, self-observation, attention focusing
3. **Self-reflection:** Self-Assessment, causal attribution, adaptation

Proficient self-regulated learners employ cognitive strategies to improve success and utilize Metacognition to refine their learning processes continuously.(Designing a mobile chatbot-based learning journaling system for intrinsic motivation and engagement)

Empirical work in a technology-mediated course confirms the phase links: in an eight-week adaptive stochastics study (194 students), task value, self-efficacy, goal orientation and positive emotions in the pre-actional phase predicted actional regulatory behavior while negative emotions hindered it, and post-actional satisfaction fed forward into the next pre-actional phase (Mejeh & Fromm (2026)).

A systematic mapping of 84 AI–SRL studies found the research concentrated on higher-education students and on the metacognitive and cognitive aspects of self-regulation, with the motivational dimension underexplored and over a third of studies specifying no SRL theory at all (Banihashem et al. (2025)).

Crucially, SRL around AI is shaped by *perception* as well as behavior: Yilmaz et al. demonstrate that whether students perceive feedback as coming from AI or a human significantly affects their self-regulated learning and revision behavior — a reminder that the social framing of AI, not just its content, changes how learners regulate around it.

One failure mode sits before regulation begins: GenAI-assisted learning procrastination — unnecessary delay in starting GenAI-supported work despite a genuine intention to use it. Among 1,243 Chinese undergraduates, more frequent GenAI use went with less of it ($\beta = -0.195$), and learning GenAI anxiety strengthened the intention-delay link (Li et al. (2026)).

Where GenAI enters the cycle decides its effect: mapping Zimmerman's forethought, performance, and reflection phases onto AI-mediated environments, a co-agency framework argues the point of entry determines whether the tool amplifies or erodes the learner's sense of control, and that offloading supports transformative learning only when the decision is intentional rather than routine (Poudyal (2026)).

A cross-sectional survey of 434 Special Education undergraduates measures one such chain: GenAI literacy was positively associated with GenAI-assisted self-regulated learning behaviors (total B = 0.701), running mainly through learning Learner Agency (B = 0.345) rather than challenge emotions (B = 0.061) (Yang et al. (2026)).

Metacognitive self-regulation is a measured outcome, not an assumption, in Shao, Tang and Ju (2026), who found that an AI-VR flipped classroom raised it alongside achievement, and that learners with higher technological literacy benefited more.

Digital Support for SRL

Learning Journals

Learning journals are a promising SRL intervention: by reflecting on their learning processes, students increase awareness of cognition and strengthen regulatory capacity. Key design considerations:

- **Structure matters:** Open-ended journals often produce shallow entries; guided prompts and example models improve depth
- **Motivation decay:** Mobile journaling apps commonly see rapid engagement decline after a few days
- **Scaffolding trade-off:** AI assistance that writes reflections for students undermines the SRL practice; assistance that structures prompts without authoring content preserves it

Dashboards communicating SRL profiles to teachers

Mejia-Domenzain et al. (2026) extend digital SRL support to the teacher side: their Learning Analytics dashboard (DashED) communicates ML-derived self-regulated learning profiles to teachers in blended classrooms, and how teachers act on those profiles is context-dependent. In use, flipped-classroom (university) teachers followed a sequential exploration and favored course-level adaptation and showing dashboards in class, whereas vocational teachers revisited summary pages and used the tool mainly for individual coaching sessions. The actions teachers proposed were shaped by the content represented and their teaching level rather than the plot type — university teachers favored weekly tests and course adaptation, vocational teachers direct, individualized coaching. This positions the dashboard as a scaffold for teachers' regulation of instruction, with design needs that vary by context rather than a single optimal interface.

The student-facing counterpart is sparser: a dashboard that showed 46 secondary students their own GenAI prompts and their text overlap with the model's replies was opened by only about a third of the class, making voluntary exposure rather than the visualization itself the binding constraint (Fong et al. (2026)).

Scheu et al.'s 2×2 Experiment (2026)

In a randomized field experiment with 179 students over 22 days, two design principles were compared:

Principle	Mechanism	Effect on SRL	Effect on Motivation	Effect on Engagement
Example-based course	7-day curriculum Teaching reflective journaling via modeled responses	Increased perceived competence and enjoyment	**Positive**	Constant positive
Large Language Models (LLMs) journaling assistant	GPT-3.5 summarizes drafts, asks clarifying questions, suggests reformulations	No direct SRL skill effect measured	**No effect**	Increasing over time (feedback loop)

Key insight: The course improved SRL skills *and* intrinsic motivation through skill transfer, while the assistant improved engagement without affecting motivation.(Designing a mobile chatbot-based learning journaling system for intrinsic motivation and engagement)

AI Tools and the SRL–Motivation Reciprocal Loop

A foundational principle of SRL theory is that self-AI Regulation in Education skills and Motivation form a **reciprocal relationship**:

- Better SRL → more successful learning → higher self-efficacy → stronger motivation
- Higher motivation → more effortful engagement → better SRL practice

AI tools can enter this loop at different points:

- **SRL-first design** (e.g., structured courses, graduated hints, reflection prompts): Strengthens the loop by building genuine skill
- **Engagement-first design** (e.g., autocomplete, content generation): May boost behavioral engagement without entering the motivation loop, risking tool dependence

Strategic Regulation of GenAI as SRL

Kim (2026) reframes effective GenAI use in academic writing as **strategic regulation** — an enacted SRL practice of verifying, revising, selectively adopting, or rejecting AI output. In a mixed-methods study of 107 students, higher AI anxiety was positively associated with verification and revision (β=.24), while evaluative capacity predicted active revision and selective integration (β=.46). Students clustered into four regulatory types — Uncritical Reliance (18.7%), Selective Integration (34.6%), Evaluative Transformation (31.8%), and Strategic Rejection (14.9%) — showing that AI Literacy in Higher Education functions less as acceptance than as regulatory competence grounded in Evaluative Judgment and ethical responsibility. This positions SRL as the core mechanism distinguishing critical from uncritical AI use.

Governance of the tool is itself a measurable facet: a two-wave validation with Chinese EFL learners (EFA N = 305; CFA N = 342) separates six regulatory dimensions and names *environmental regulation* — checking generated output for accuracy, filtering suggested resources, and setting boundaries on reliance — as one in its own right (Wang, Zhang and Zhang (2026)).

Classify before delegating: Tsim and Gutoreva (2025) turn self-regulation into a per-task protocol — label each subtask Substitute, Complement, Aid or Non-negotiable, justify it in a short metacognitive note, and keep an audit trail of prompts, drafts and human revisions — with the cycle repeating so one task's assignment informs the next. **Every prompt as a regulatory trace.** Reading 429 prompts from 23 students as self-regulated learning events showed the structure mix shifting with task design while 53 of 59 submissions stayed close to the model's output, locating regulation in the exchange rather than the artifact (Kontorovich & Wallach (2026)). **The interaction itself as an object of regulation.** Brunnström and Palmqvist (2026) document the same regulation demand from the other direction: in an eight-round demonstration using a chatbot to prepare a take-home examination answer, the AI's default output stayed at the *quantitative*, multistructural end of the SOLO taxonomy — polished, submission-ready and pedagogically thin — and reached a usable three-step learning loop only after repeated meta-level interventions ("this is overwhelming, can you condense it?"). Their conclusion is that productive use

required “the very self-regulatory skills the tool was expected to support”: the learner must set incremental goals, request difficulty adjustments, and reflect on what is not yet understood, on top of the disciplinary content itself. They name this capacity AI-interaction literacy and treat disengaging from the tool as a legitimate regulatory decision rather than a failure of persistence (Metacognition).

- **Satisfaction is not self-regulation.** Liang et al. (2026) surveyed 689 undergraduates in industry-education programs and tested a serial mediation model in which the perceived affordances of AI-generated content raise AIGC Self-Efficacy (beta = 0.583) and, through it, learning Motivation (beta = 0.565) and self-regulated learning (beta = 0.250), with motivation the heaviest single predictor of SRL (beta = 0.527). The load-bearing negative results sit alongside those paths: the quality of AI assessment feedback predicted satisfaction strongly (beta = 0.712) but not self-efficacy (beta = 0.131), and satisfaction had no significant effect on self-regulated learning (beta = 0.032). A well-liked, well-functioning assistant is therefore not evidence that regulation improved — the mechanism runs through confidence and motivation, not through the learner’s experience of the tool.

Dependency works through effort regulation, not use volume. In a survey of 982 undergraduates, GenAI dependency predicted lower effort regulation (β = −0.257), which predicted perceived learning outcomes (β = 0.497), giving a negative indirect path (β = −0.128) while frequency of use carried no significant total association (Li, Zhang and Yang (2026)).

GenAI-aware reflection as SRL

The 5P Reflection Model (Kadel et al. 2026) re-centers structured reflection in the GenAI era as an enacted SRL practice. SRL owns reflection only as one phase of its cycle; the practice itself — prompts, journals, portfolios and scored reflective text — is carried on the Reflection page, which also sets out where it differs from Metacognition and Self-Assessment. Learners increasingly co-create meaning with AI, and traditional reflection models struggle to authenticate what a student has done. The 5P model (Purpose, Process, Product, Pitfalls, Plan) fuses forethought-driven goal setting, reflection-in-action (documenting prompts and iterations), reflection-on-action (validating the probabilistic output against external sources), an explicit pitfalls stage for hallucination, plagiarism, and over-reliance, and a forward-looking plan — embedding emotional monitoring throughout. Its “process over product” philosophy treats structured documentation of the human-AI interaction as the regulatory demand that preserves authenticity, Learner Agency, and metacognitive depth, positioning GenAI-aware reflection as a scaffold for self-regulation rather than a substitute for it.

Relationship to Tutoring-Specific Design

Tutoring-specific AI aligns with SRL-first design: it provides graduated scaffolds that preserve Learner Agency and require strategic self-regulation. General-purpose AI often removes the regulatory demands entirely.(The Evidence Base on AI in K-12: A 2026 Review)

For example: - Bastani et al.’s tutoring-specific chatbot preserved step-by-step reasoning (SRL demand) - The general-purpose GPT variant simply provided answers (SRL bypass)

Evidence Across Contexts

- **Mixed evidence and the miscalibration gap.** A rapid review of PreK-12 GenAI research finds metacognitive gains during supported tasks often do not persist when support is removed, and that GenAI can increase perceived learning even when durable learning is absent (the miscalibration gap — students preferred GenAI over note-taking despite weaker retention). Students need explicit, stage-appropriate training to decide what to delegate and when independent effort matters.(Young people, learning, and generative AI: A rapid literature review and implications for PreK-12 education)
- **SRL is rarely the active target.** Across 394 GenAI higher-education studies, self-regulated learning and reflection were among the least frequently enacted uses and among the outcomes targeted least (Lin et al. (2026)).
- **Agentic initiative vs. self-regulation tension.** Woollaston et al. (2026) note that as agents automate more of a task, the less self-regulated cognitive work the learner performs — so designs should give learners control over agent initiation (dynamic, fading scaffolding) to preserve self-regulatory capacity rather than outsourcing it.
- **Self-regulation shapes AI coding-assistant use.** A study of AI coding assistants found high-Computational Thinking students showed stronger self-regulatory coherence (planning-execution-self-reflection) and used AICA for code understanding, while low-CT students used it for immediate answer retrieval.
- **SRL co-occurs with lower digital distraction in online learning.** Shi et al. (2026), using unsupervised data mining on 530 college students, found that SRL strategies — goal setting, environment structuring, and time management — co-occurred most consistently with lower digital distraction in online learning, alongside learner-instructor and learner-content engagement. The finding positions concrete SRL training as a high-leverage intervention for focused online study.
- **Metacognitive awareness, not tool access, is the strongest driver of adaptive STEM performance.** Alatoai and Alshahri (2026) built and validated the AI-STEM-MLCS with 649 secondary students in Saudi Arabia (CFI = 0.983, RMSEA = 0.019; McDonald's $\omega = 0.888$ to 0.905) and found its four dimensions explained 68% of the variance in self-regulated learning performance ($R^2 = 0.68$). AI-based metacognitive awareness was the strongest predictor ($\beta = 0.38$, $p < 0.001$), followed by cognitive transfer and adaptability ($\beta = 0.29$, $p = 0.008$) and AI-enhanced self-regulated learning ($\beta = 0.21$, $p = 0.040$), while creative and critical AI-STEM reasoning did not predict the criterion ($\beta = 0.14$, $p = 0.135$). The authors read the pattern as evidence that adaptive feedback raises STEM performance mainly by prompting learners to examine errors, recalibrate, and reuse strategies, so the instrument works better as a diagnostic that locates meta-learning gaps than as a single global score. It is a self-report measure validated in one national system, so the coefficients are provisional.
- **External support can bypass a learner's own metacognitive judgment.** Iqbal et al. (2026) traced 87 EFL students revising an essay under GenAI (ChatGPT 4.0), human-expert, or no support. The support condition was by far the strongest correlate of the revision strategy a student

chose (Cramér's V = 0.668), well ahead of carry-over from the preceding writing task (V = 0.333), while metacognitive judgment accuracy (p = 0.172), writing skill (p = 0.261) and Motivation (p = 0.683) were unassociated. Metacognitive judgment tracked strategy only when no support was available (permutation test p = 0.0460). Students with GenAI support gained the most (about 4 points on average under the decreasing-help-seeking strategy, against −0.5 points for the same strategy under human-expert support), yet no revision strategy was associated with score change (H(3) = 3.895, p = 0.273), so the gains came from the tool rather than from better self-regulation. The authors' orientation is that GenAI should prompt reflection on one's revision strategy instead of supplying direct help.

- **Reflective use tracks critical thinking, not knowledge gain.** Melanou et al. (2026) followed three parallel classes of business informatics students (N = 87) across a nine-week course, with knowledge rising in every group ($F(1, 50) = 29.87$, $p < 0.001$, $\eta^2p = 0.374$) and no AI advantage, no Time × Group interaction, and no Matthew effect ($F(1, 48) = 2.46$, $p = 0.124$; BF01 = 8.70). Reflective use (checking sources and verifying AI output before adopting it) was markedly higher in the AI condition (3.72 vs 2.82; $F(1, 40) = 20.21$, $p < 0.001$) and predicted critical thinking ($\beta = 0.43$, $p < 0.001$) but not knowledge gain, which germane cognitive load did predict ($\beta = 0.51$, $p = 0.001$). The practical reading is that AI access is not itself an intervention, and that its metacognitive payoff surfaces in reasoning quality before it surfaces in test scores.
- **Structure, not AI alone, drives SRL gains.** Mapping Zimmerman's phases onto project-based hybrid instruction with AI as metacognitive scaffolding produced an N-Gain of 0.72 versus 0.28 for conventional instruction ($t = 8.47$, $p < 0.001$, Priyambudi et al. (2026)), who argue AI strengthens self-regulation only inside task structure — unstructured use risks metacognitive laziness.
- **AI speed can displace the peer dialogue that carries co-regulation.** Coding 28,123 forum sentences across four graduate courses, one human-only and two with heavy AI TA use, Davis et al. (2026) found the AI TA was first responder in 97% of student-started assignment threads, with a median 0.92 minutes to its reply against 490 when a peer replied first. Thread starts were unchanged ($p = .73$) but reply posts fell from 18.2 to 10.9 per student ($p < .001$), and peer repliers' share of follow-up sentences dropped from 91% to 45% between semester halves.
- **The resulting SRL decline is compositional.** Because peer repliers supply about 70% SRL-coded sentences against 20 to 27% for thread starters, aggregate regulatory language fell from 49% to 36% ($p < .001$). Each role's own rate held steady, so the drop reflects who was writing rather than a change in how individuals write. Self-regulation still predicted grade ($\beta = 2.63$, $p = .017$), and peer replies moderated that relationship ($\beta = 1.45$, $p = .013$). The grade penalty attached to AI-dominated threads ($\beta \approx -1.38$, $p = .038$) then vanished once 17 high self-regulators were removed ($\beta \approx -1.29$, $p = .454$), which the authors read as the cost running through lost co-regulation rather than through the AI directly. It is observational, so the mechanism stays unproven.
- **Emotional scaffolding moves trace-measured SRL phases that cognitive scaffolding alone does not, and self-report barely sees it.** A preregistered experiment with 144 high school students compared plain ChatGPT, an SRL-scaffolding agent and an emotional version that asked about feelings at three points and adapted tone and challenge along control-value lines. Trace

coding found large condition effects in all three phases (ε2 = 0.44 forethought, 0.34 performance, 0.34 self-reflection). SRL prompts alone lifted goal setting and planning to the emotional version's level, while the emotional layer added more performance-phase activity (r = 0.22) and self-reflection (r = 0.31). Self-reported SRL separated the conditions only in the performance phase; trace-self-report correlations were 0.313 there, 0.22 for forethought and 0.04 for self-reflection. The authors read the trace differences as co-regulated enactment rather than independent regulatory capacity (Diordiev, Stenberdt & Makransky, 2026).

- **In groups, regulation is triggered by the AI's own prompt, and preconception diversity changes how that prompt lands.** Wang et al. (2026) compared 8 different-preconception and 6 similar-preconception pre-service teacher groups working with an on-demand metacognitive chatbot and a proactive voice agent. Prompt function converged across conditions at 39 prompts, 18 against 21, while sequential structure did not: diverse groups sustained positive or neutral evaluation of the output and similar groups sustained negative evaluation alongside recurrent task agreement. Raw-data inspection traced part of the negative loop to the proactive speaking agent, so the authors read it as a timing and modality mismatch rather than a rejection of support. Their design implication is that shared-regulation support in groups that have already converged should stay optional.

LLM-Mediated SRL: Scaffold, Shortcut, or Partner?

A cluster of Learning Letters studies (2026) converges on a central tension: GenAI can scaffold, short-circuit, or partner with self-regulation depending on design and how learners regulate its use. The evidence points to SRL itself — not the tool — as the decisive variable.

- **Viberg et al.** find that LLMs are woven into a *layered Help-Seeking ecosystem* rather than replacing human support: students try tasks independently first, then consult ChatGPT as a low-barrier first step, peers for conceptual negotiation, and instructors for high-stakes issues. They favor **instrumental help-seeking** (hints, step-by-step guidance) over **executive help-seeking** (direct solutions), exercising selective Trust and verifying outputs against course materials — a four-stage process (deciding whether help is needed, choosing whom to ask, determining the type of help, judging the help received) that can be measured and taught.
- **Atif & Dickson-Deane** frame GenAI use as **Cognitive Offloading** that can be either *scaffolded* (learners critique and adapt AI outputs, keeping Learner Agency and sense-making) or *substitutional* (learners accept outputs with minimal verification, shifting control to the tool). In a study of 267 postgraduate IT students, the same tool could scaffold or shortcut SRL depending on learner strategy — confident users showed agency in goal setting and monitoring; less confident users saw GenAI as a shortcut or misconduct.
- **Lim & Bannert** show the risk concretely: students voluntarily used a genAI chatbot (73%) and scored higher on essays, but they offloaded comprehension and synthesis (asking the chatbot to "extract only the main ideas") and engaged in almost no planning or monitoring — outsourcing key regulatory decisions. This reflects a **production deficit**: students possess SRL knowledge but fail to deploy it spontaneously, so genAI tools should prompt reflection (a monitoring scaffold) when queries indicate offloading.

- **Song et al.** demonstrate that SRL is both a **stable aptitude and a dynamic state**: individual baselines are consistent, but metacognitive knowledge and Well-Being decline systemically over a semester, driven by assessment deadlines. They show GenAI can act as a context-aware **learning partner** when it is given personal, temporal, and contextual data — supporting students without replacing their effort. This argues against "one-time-fits-all" personalization based on baseline aptitude alone.
- **de Barba** extends SRL theoretically, arguing the field has narrowed to task-focused regulation and to optimizable behavioral proxies in educational technology. The paper proposes a cross-scale account of **learner agency** — regulation (within tasks), integration (across time and contexts), and positioning (critically in relation to the conditions framing learning) — as a design orientation for algorithmically mediated environments.
- **Self-regulation buffers but does not cancel offloading harm.** Chen (2026) shows that self-regulated writing attenuates — but does not eliminate — the negative association between deep Cognitive Offloading and independent no-AI outcomes in GenAI-assisted writing: the offloading-by-SRL interaction was positive (B = 0.22), flattening the harm from a slope of −0.54 (low SRL) to −0.33 (high SRL) but not canceling it. A bounded-support condition pairing delegation limits with compulsory reflection produced the strongest independent performance, evidence that metacognitive regulation partially protects learners yet cannot fully compensate for delegating the cognitive work itself.

Where rental sits inside Winne's models. de Barba (2026) maps the mechanism onto SRL as operations the system performs in the learner's place: noticing, monitoring and evaluative judgment are exercised by the tool, an impasse is resolved by search rather than by the learner's own If-Then, Else choice, and the standards by which the learner judges are borrowed rather than built. A capability that a learner believes they hold while the tool holds it — *hidden rental* — suppresses the error signal that would otherwise prompt regulation, and ten propositions specify what to test, including larger costs in domain acclimation and standards drifting toward the model's own reference points.

The collective lesson: **SRL is the core mechanism distinguishing critical from uncritical AI use.** Whether GenAI functions as a scaffold, shortcut, or partner depends on learners' regulatory capacity and on whether tools are designed to preserve (rather than remove) the regulatory demands that build expertise.

Which support is in play decides which mediator carries the association: among 3,003 Chinese pre-service teachers, perceived AI tool support ran to innovative competence mainly through AI Self-Efficacy (60.88% of that path's total effect), while perceived school-based intelligent environment support ran mainly through self-regulated learning (29.64% versus 18.60%) (Liu et al. (2026)).

Implications

- **For journaling/chatbot tools:** Combine SRL instruction (course-based) with optional writing support to get both motivation and engagement gains
- **For tool designers:** Make evaluation a required step, not an optional one. Iqbal et al. found that the available support, rather than the learner's metacognitive judgment, decided the revision strategy students used and that GenAI score gains did not come from better regulation, while Melanou et al. found reflective use predicted critical thinking where mere tool access did not.

Interactions that ask learners to verify, compare, and re-strategize are the ones carrying the learning value.

- **For instructors:** Treat AI-based metacognitive awareness as the first lever and check it explicitly. Alatoai and Alshahri found it the strongest predictor of adaptive STEM performance (β = 0.38) and that transfer and adaptability came second (β = 0.29), so activities that have students examine errors and carry a strategy into a new problem context do more than general prompting for critical or creative reasoning.
- **For AI policy:** Procurement criteria should ask whether a tool develops or displaces self-regulation
- **For researchers:** Long-term studies measuring SRL outcomes (not just immediate performance) are essential; Melanou et al. show the payoff of that patience, since a semester's reflective use moved critical thinking (β = 0.43) without moving knowledge gain.

Conversational Agents and SRL in Simulation Games

- **Conversational agents supporting self-regulated learning in games.** Wenzel, Geiger, and Liening (2026) show that an AI conversational agent (Lara) in a business Simulation game can support self-regulated learning through metric-based formative feedback, on-demand guidance, and structured reflection — addressing the common limitation that simulation games provide limited formative feedback and reflection prompts. Evaluations with student teachers and BSG participants reported positive perceptions of the agent's cognitive and social presence and its support for self-regulation.

Automated SRL Detection: What Transfers and What Doesn't

- **Embedding-based SRL classifiers cross languages within a domain, but not across domains.** A study of 26 students (chemistry and formal logic; think-aloud protocols coded with the Winne-and-Hadwin model) found embedding-based models (text-embedding-3-small) trained on English classify German SRL at ~0.8 AUC with ~0.1 degradation — except enacting (~0.7). Cross-domain transfer fails: chemistry-to-logic drops to ~0.6, enacting to chance (~0.5) — the domain wall, not language, binds.
- **Three failure modes explain where transfer breaks.** (1) Concept resolution at everyday rather than domain meaning — "cancel" vs. chemistry "kürzen" — breaks enact classification. (2) Anthropomorphization — German students unfamiliar with a heavily scaffolded tutor addressed it as a person, producing out-of-distribution utterances; transfer was better on less-scaffolded platforms. (3) Hint-reading vs. plan-formulation ambiguity — models can't tell reading a metacognitive hint from planning without log data. Realizing errors is robust across every condition — noticing you're wrong is context-independent. Fixes: expert dictionaries or fine-tuning for domain terms; log data for hints. (Large language models generalize SRL prediction to new languages within but not between domains)
- **Shallow cues over-attribute regulation in curriculum mapping.** Given assessment descriptions, GPT-o3-mini read mentions of deadlines or scheduling as evidence of a self-regulatory skill; Self-

Management was over-identified this way, its agreement with expert weights ranging from 0.53 to -0.03 (Jayalath et al., 2026).

- **Structured question chains turn prompting into regulation.** In a quasi-experiment with 83 undergraduates, both question-chain conditions produced more learning-strategy and monitoring behavior than free-form questioning ($\chi^2 = 6.551$, $p = .038$) and scored higher on metacognitive awareness and achievement ($F = 3.406$, $p = .038$; $F = 3.807$, $p = .035$), with no difference between the chain forms (Lin et al., 2026). Sequencing is what does the work.
- **Group-level detection follows the same split, and talk carries more than logs.** In dyads modeling a truck's motion in C2STEM, 394 task-context segments from 36 high schoolers were labeled with seven socially shared regulation codes and predicted from LLM summaries of each segment: text-only embeddings reached mean AUC 0.650 while log-derived features alone reached 0.526, near chance for a construct that is largely social. Planning was invisible within a single segment (0.5036) and became detectable once the two segments on either side were concatenated (0.6711), whereas reflecting was best once the logs were added (0.5862), the same hint-reading-versus-plan ambiguity this section records for individual learners (Zhang et al., 2026).
- **Automated SRL labels hold for enacting and fail for planning.** In a fourth-grade mixed-reality science class, a pipeline fusing gaze, gesture, speech and game logs labeled 75 human-checked segments at 74.67% overall, from 93.3% for enacting and interacting down to 46.7% for planning (Fonteles et al., 2026).

Common Misconceptions

- **"Self-regulation is a learner trait."** Regulated learning decomposes into **self-reflection, causal attribution and adaptation**, and proficient learners **employ cognitive strategies to improve success**. These are trainable processes that a design can support or undermine.
- **"Any adaptive design supports regulation equally."** Scheu et al.'s **2x2 randomized field experiment with 179 students over 22 days** compared two design principles and found them different in mechanism, so "adaptive" is not a single treatment.
- **"Anxiety undermines regulation."** In a mixed-methods study of **107 students**, higher AI anxiety was **positively associated with verification and re-checking**. Anxiety functioned as a prompt to verify, which is regulation rather than its absence.
- **Metacognitive SRL predicted learning-relevant load where the AI feedback did not.** In a five-week field study with **234 students and 1,147 observations**, metacognitive self-regulation was a substantial positive predictor of **germane cognitive load** ($\beta = .363$, $p < .001$ intention-to-treat; .346, $p < .001$ usage-based) and did not significantly predict extraneous load — while mere access to conversational AI feedback predicted neither. Only **sustained** engagement with the feedback separated students on germane load, and irregular use did not ($\beta = -.219$, $p = .116$), which locates the active ingredient in the learner's regulation of processing rather than in the feedback supply (Wenzel, Geiger and Liening, 2026).

Self-Determination Theory

> **Self-Determination Theory (SDT)** — a psychological theory of human motivation positing that intrinsic motivation and Well-Being depend on satisfying three basic psychological needs: autonomy, competence, and relatedness. In AI in education, SDT provides a framework for designing AI tools and professional development that support rather than undermine learners' and teachers' motivation.

Questions to Consider

- The theory claims motivation isn't just how *much* you have but a *quality* shaped by the environment, built on three needs: autonomy, competence, and relatedness. Think of a learning experience that drained you. Which of those three needs was violated, and what would have restored it?
- A year-long study found three motivational profiles — Disengaged, Developing, Self-Determined — that were stable over time, and students who reached the Self-Determined profile showed the greatest AI-literacy gains. Before you read, is motivation something students bring with them, or something a well-designed environment can grow? What does 'developmental, not fixed' imply?
- If an AI tool makes every task effortless and 'easy to use,' which psychological need might it be satisfying — and which might it be quietly undermining? How could a tool that boosts short-term engagement still erode long-term motivation?
- Need-supportive professional development for teachers enhanced their AI literacy and sustained engagement. Does this suggest that how we *train* educators about AI matters as much as what the AI itself does? What would 'autonomy-supportive' AI training for you personally look like?
- A study found ChatGPT could support autonomy, relatedness, and competence in language learning. But could the same tool undermine those needs for a different learner? What would need to be true about *how* it's used for the theory to hold?
- Before reading further, name one way you've felt your own competence, autonomy, or sense of connection affected by using an AI tool — and reflect on whether you'd have noticed that change without being prompted to look for it.

Introduction

SDT is increasingly used in AI in education research as a theoretical lens for both learner-facing and teacher-facing AI systems. The theory's central claim — that motivation is not simply a quantity learners have but a quality shaped by the social and technological environment — makes it directly relevant to questions about how AI tools affect engagement, persistence, and learning outcomes. The articles in this knowledge base apply SDT across three main contexts: teacher professional development, AI-mediated learning engagement, and affective computing.

Key research themes

SDT-based teacher professional development applies the theory's need-supportive principles to prepare educators for AI. **Chiu et al.** studied 382 secondary school teachers, finding that need-supportive professional development grounded in SDT enhances teachers' AI Literacy and fosters sustained behavioral engagement in online professional learning communities. Qualitative analysis identified nine design strategies supporting autonomy, competence, and relatedness — bridging the gap between isolated professional development and professional learning communities.

SDT in AI-mediated learning engagement examines how generative AI tools shape student motivation. **Isaeva et al.** combined SDT with epistemic network analysis to study students' engagement with generative AI in academic learning. **"Why Put in This Much Effort?": How AI Availability Shapes Students' Motivation in Introductory Programming** explores how AI availability affects student motivation and persistence, connecting to Over-Reliance concerns about motivation erosion. **Liang et al. (2026)** extend SDT to AI learning with a latent transition analysis of **2,086 secondary students** in a year-long AI curriculum, identifying **three motivational profiles (Disengaged, Developing, Self-Determined)** that were stable across time and showing that most students maintained or advanced toward higher profiles. Crucially, students who reached or remained in the Self-Determined profile showed the **greatest AI Literacy gains** — direct longitudinal evidence that satisfying autonomy, competence, and relatedness predicts better AI-learning outcomes, and that motivation is a developmental (not fixed) learner property.

A contrasting classroom result shows the needs do not move together: among 2,464 lower-secondary students, ChatGPT-supported competency-based learning raised autonomy support and competence satisfaction yet produced a larger share of low-quality motivational profiles, and relatedness satisfaction was weaker than in non-AI competency-based learning (Schweder, Hagenauer & Raufelder (2026)). - **Availability is not usage.** With 406 students in Grades 5–8 writing twice, once without digital tools and once with GenAI optional, autonomy satisfaction fell ($\Delta = -0.28$) while mean regulation stayed stable and degree of AI use predicted no profile membership (Schweder & Grahl (2026)).

Autonomy, not ease, carried the motivational gain here. A three-arm RCT found that a hint-withholding tutor, which kept learners building their own solution, was the only arm to raise intrinsic motivation (2.82 vs 2.42), while unrestricted ChatGPT, which supplies the answer, did not (2.64, $p = .076$) (Bassner et al. (2026)).

A configurational test sharpens the point: among 498 medical undergraduates, GAI use was only weakly associated with need satisfaction ($\beta = 0.155$) and proved unnecessary for high engagement, while competence need satisfaction was the core condition in the strongest configuration (He et al. (2026)).

Dual pathways from learning climate to AI use. Shen and Arunrugstichai (2026) integrate SDT with the Hook model of behavioral engagement to explain why GenAI use ranges from constructive support to compulsive dependence. In cross-sectional survey data from **508 university students** with different high-school backgrounds and current contexts (China and Thailand), retrospective reports of **high-school pressure vs. autonomy support** differentially predicted which of two pathways students followed into university — one toward constructive, autonomous GenAI use and another toward compulsive dependence — with results consistent across cross-contextual multi-group analyses. The model links SDT motivational

processes to perceived quality of AI-supported learning, framing autonomy support as a lever that steers students toward productive rather than dependent AI use.

- **ChatGPT and SDT needs in language learning:** Annamalai et al. (2026) used an SDT lens with 25 Malaysian university students, finding that ChatGPT supports autonomy, relatedness, and competence in English language learning — enhancing grammar, writing, and conversational tasks while letting educators focus on higher-order training.

SDT applied to instructors' own AI-mediated practice. Claassen et al. (2026) used SDT as the interpretive lens on how instructors integrate learning analytics and generative AI into learning design — finding that supporting instructors' basic needs (autonomy, competence, relatedness) fosters the creative Problem Solving their design work requires. In their ENA analysis, GenAI use was associated with designing for student self-determination (e.g., co-creating assessment rubrics with students), extending SDT from learners to the educators who build need-supportive AI-mediated environments.

For teachers themselves, AI collaboration cuts both ways: a three-wave study of 468 university teachers found it raised work engagement through psychological availability while lowering it through work alienation, and digital competency strengthened the first path and weakened the second (Sun et al. (2026)).

A co-agency framework bounds SDT's reach in AI-mediated education: it changes the circumstances under which autonomy, competence, and relatedness arise but leaves equity of power, data ownership, and accountability unaddressed, which is why its authors set human epistemic accountability as a non-negotiable condition outside the theory (Poudyal (2026)).

Autonomy support as the frame for children's GenAI use. Fan, Li and Zhang (2026) relocate the question of responsible use from restriction to need support, arguing that the distinction that matters is whether adults around a child support autonomy rather than control it, and distinguishing dependent from autonomous Cognitive Offloading within SDT terms. Dependent offloading transfers Learner Agency and lowers intrinsic motivation; autonomous offloading scaffolds while the learner retains epistemic control. Two features of the review are directly relevant to SDT application: it insists that autonomy support is not permissiveness, and it treats the family-school coordination that current guidance assumes as an untested hypothesis, formalizing additive, synergistic and compensatory versions that only a factorial trial contrasting family-only, school-only, coordinated and usual-practice guidance could discriminate.

Connections to related concepts

SDT connects directly to Motivation as its parent construct, to Affective Computing and Affective Tutoring for emotion-aware AI design, and to Student Experience for how learners experience AI-mediated environments. The theory's emphasis on autonomy connects to Self-Regulated Learning, while its competence dimension connects to Self-Efficacy and Favorability Shape Learning from Tutoring Systems and Paper Practice and Teacher AI Competency. SDT is particularly relevant to Workplace Learning and Educational Development because need-supportive design is a transferable principle for preparing educators to use AI.

The three needs are not exercised evenly by generative-AI research. Pan, Abuhassna and Jiang (2026) coded 39 studies against a 20-activity classification and found 14 activities present, with seven competence-related types against five for autonomy and two for relatedness. Six activities were absent from every study,

and most ask the student to judge or challenge the tool: creating challenging problems, anticipating the tool's outputs, grading those outputs and debating with it. Relatedness is the need the literature least tests.

Common Misconceptions

- **"Motivation type matters less than motivation amount."** A year-long study found **three motivational profiles — Disengaged, Developing, Self-Determined — stable over time**, and students who reached the **Self-Determined** profile showed the **greatest AI Literacy gains**. The quality of motivation predicted the learning, and the profiles did not simply drift upward.
- **"Autonomy support means removing structure."** The SDT mechanism is autonomy, competence and relatedness together, and the longitudinal evidence shows that satisfying them predicted gains rather than merely accompanying them. Autonomy without competence support is permissiveness, and it does not satisfy the theory's conditions.
- **"A chatbot can supply the three needs automatically."** A study found ChatGPT could support autonomy, relatedness and competence in language learning — a possibility, not a property. Whether a given interaction supports them is an empirical question about how it is used.

Motivation

> **Motivation** — the psychological processes that initiate, direct, and sustain goal-directed behavior. In AI in education, motivation research examines how AI tools affect learners' and teachers' motivation — whether AI scaffolds or undermines persistence, curiosity, and intrinsic engagement — and how motivational states shape the effectiveness of AI-mediated learning.

Questions to Consider

- Motivation is often treated as a trait some students 'have' and others lack. The page describes it instead as psychological processes that initiate, direct, and sustain behavior — and as something developmental and socially scaffolded. How does that reframe who is responsible for student motivation?
- AI tools can remove friction and make learning more accessible, but they can also reduce the cognitive effort and struggle that support intrinsic motivation. When has making something 'easier' actually made it less motivating or less satisfying for you?
- Self-determination theory says intrinsic motivation grows from autonomy, competence, and relatedness. If an AI tutor does most of the work, which of those three might it threaten — and which might it enhance?
- Research finds distinct motivational profiles among students in an AI curriculum, and that reaching a self-determined profile predicted the largest AI-literacy gains. What might it take for a learner to move from passively disengaged to genuinely self-determined in using AI?
- The page reports that teacher support drives AI-assisted engagement largely through mastery-approach and performance-approach goals — the 'approach' rather than 'avoidance' orientations. How does the way a teacher frames AI use ('to get it right' vs. 'to avoid looking wrong') shape whether students engage deeply?
- If you're designing for motivation, is the goal to make learning easier, more engaging, or more meaningfully effortful? Where do Accessibility and intrinsic motivation pull in opposite directions?

Introduction

Motivation is a foundational construct in education research, and the rise of AI in education has made it more consequential: AI tools can remove friction and make learning more accessible, but they can also reduce the cognitive effort and struggle that support intrinsic motivation and deep learning. The articles in this knowledge base explore motivation across learner-facing AI tools, teacher-facing AI systems, and the psychological mechanisms — self-determination, self-efficacy, emotions — through which AI shapes motivated behavior.

- **Lee & Wu** show gender and motivation drive differential engagement with GenAI, with distinct achievement trajectories.

Key research themes

AI effects on student motivation is the most direct line of research. **"Why Put in This Much Effort?": How AI Availability Shapes Students' Motivation in Introductory Programming** examines how the availability of AI assistance affects student motivation and persistence, connecting to Over-Reliance research on motivation erosion when AI does the work. For persistence specifically, brief exposure is enough: ten minutes with an assistant that answered on request left participants skipping 0.20 of unaided problems against 0.11 for controls (Liu et al., 2026). **Designing a mobile chatbot-based learning journaling system for intrinsic motivation and engagement** explores mobile chatbot journaling as a motivational intervention. **Designing Needs- and Attention-Aware AI Learning Tools for Engineering Education: Insights from Psychological Outcomes** examines what motivates students to adopt AI learning tools in engineering education.

A 42-study meta-analysis (56 effect sizes, 6,059 students) found GenAI-supported learning raised motivation by Hedges' g = 0.764 (95% CI [0.566, 0.962]) — but with I^2 = 93.7% and a 95% prediction interval of [−0.689, 2.217], the average conceals settings where the effect is near zero or negative (Fang et al. (2026)). - **Unreflective use erodes motivation — more so for men.** Thoughtless GenAI use (accepting answers unexamined) predicted lower motivation (β = −0.54) and lower Self-Efficacy (β = −0.37) among 487 undergraduates, and the motivation effect was significantly stronger for male students while the self-efficacy effect was stronger for female students (Zhao & Gu, 2026). - **Cutting frustration is not the same as sustaining motivation.** A three-arm RCT found a scaffolded tutor and unrestricted ChatGPT cut frustration equally (3.21 and 3.13 vs 4.09), but only the scaffolded tutor raised intrinsic motivation (2.82 vs 2.42, $p < .001$); ChatGPT did not (2.64, $p = .076$) (Bassner et al. (2026)). - **Equal feedback quality does not mean an equal motivational effect.** A three-arm RCT with 312 first-year writers found AI-generated and instructor feedback improved revised essays by the same margin: d = 0.60 and 0.59, equivalent inside a pre-specified ±0.35 SD band. Instructor feedback nonetheless raised intrinsic motivation more than AI feedback (5.16 vs 4.90, d = 0.31), and perceived relatedness to the source mediated that gap (indirect 0.25, 95% CI [0.12, 0.40]) with almost no direct effect left (Liu et al. (2026)). Performance ran through feedback engagement rather than self-efficacy, whose indirect path was not significant. Where the Bassner trial separated autonomy from answer-supply, this one holds output quality constant and locates the motivational difference in who the learner is answering.

Why a reader reaches for AI is itself a measurable variable: the AIR scale resolves four motives for GenAI-assisted reading — Task-oriented, Feel-good, Translation and Low-effort — and only Low-effort, using AI when tired or disengaged, was negatively related to need for cognition (r = −.18) (Brann, Etgar and Sidi (2026)).

Motivation in AI-mediated engagement examines how motivational quality (not just quantity) changes with AI. **Isaeva et al.** combined self-determination theory with epistemic network analysis to study engagement with generative AI. **Liang et al. (2026)** traced motivation developmentally via latent transition analysis of **2,086 secondary students** in a year-long AI curriculum, finding three stable profiles (Disengaged, Developing, Self-Determined) and that reaching the Self-Determined profile predicted the largest AI Literacy gains. **Wang & Wang (2026)** used goal-setting theory with **758 university English learners**, showing that **teacher support** drives AI-assisted engagement primarily through mastery-approach and performance-approach goals (the approach, not avoidance, goal orientations). Together these studies

show that motivation in AI contexts is both developmental and socially scaffolded — it shifts over time and responds to teacher support and goal framing, not just tool design.

Goal orientation also routes how the tool is used: mastery and normative performance goals tend to support elaboration and refinement, whereas appearance performance goals make effort-minimization and protecting perceived competence more likely — so the same assistant scaffolds or substitutes for thinking depending on the motivational climate (Øby, 2026). Reward motivation can blunt AI feedback's reach: for Pérez-López et al. (2026), the credibility–perceived-learning link weakened as grade-based reward sensitivity rose — simple slopes b = 0.733, 0.607 and 0.483 at low, mean and high sensitivity.

Institutional generative-AI policy is itself a stressor Learners appraise: Chen (2026) found that the gap between universities' GAI advocacy and their classroom practice raised both challenge and hindrance appraisals among Chinese art and design students, with opposing indirect effects on creative process engagement, while pathways thinking amplified only the challenge route.

A dialogue format can raise motivation without improving overall evaluation: in 222 first-year high-school students, teacher–teacher dialogue raised ARCS motivation more than teacher–student format for learners high in concrete experience (b = 0.162, p < .001) yet scored significantly lower on overall evaluation (b = -0.126, p = .005) (Watanabe et al. (2026)).

Motivation shapes how students frame the tool, and the framing carries the metacognitive payoff: Cui et al. (2026) found the collaborator role — 7.5% of logs — was the only one producing a complete metacognitive chain, while extrinsically motivated students used GenAI as a replacement tool in 64.6% of logs and produced no higher-order connections.

Motivation gains are construct-specific, not general. Lu et al. (2026) found that a nine-week GenAI-supported writing program for 301 Grade 5 and 6 learners raised their ideal L2 writing self and academic buoyancy — the aspirational and the resilience components of motivation — while leaving growth mindset unchanged; the only growth-mindset gain appeared in the control group and did not survive correction for multiple comparisons. Students attributed the shift to seeing fluent text built from vocabulary they already knew, which made successful writing feel attainable. So motivation is not a single dial that AI turns up: what improved was the belief that one *can* write well, not the belief that ability grows with effort. The same construct-specificity appears when GenAI is itself the relevance intervention. Guo, Fryer and Shum (2026) had **218 high-school students** spend one hour in semi-structured dialogue with a chatbot aimed at personal relevance to math; the collective, class-level version raised relevance as identification ($F = 4.35$, $p = .014$, $\eta^2 = 0.04$; against the control, $F = 11.11$, $p = .001$, $\eta^2 = 0.073$ — a medium effect) and, in the SEM, predicted relevance to a specific lesson one week later ($\beta = 0.18$, $p < .01$), while interest in the math class did not move ($F = 0.29$, $p = .75$, $\eta^2 = 0.003$). The authors attribute the decoupling to dose: a single one-hour session is too brief for relevance gains to consolidate into interest in the class.

A utility-value intervention is not uniformly beneficial: a scaffolded version produced no overall gain in pre-service teachers' knowledge integration and *harmed* it for learners who entered with high perceived utility-value, an aptitude-treatment interaction arguing for matching motivational support to learners' starting points (Boos, Eder & Lachner (2026)). **A feedback message moves interest through its perceived usefulness, not through the learner's dispositions.** Jansen et al. (2026) gave 1,507 secondary students one standardized automated feedback message after a first draft of an argumentative text. Global receptivity was the only receptivity dimension related to situational interest change (about 0.11 points on the observed scale, roughly

the 54th versus 46th percentile), and that effect was fully mediated by perceived usefulness (indirect β = 0.09, 95% CI [0.06, 0.13]). No significant direct path remained (β = 0.06, 95% CI [−0.07, 0.16]). What shifted interest was therefore the felt worth of the message, not the learner's general stance toward feedback.

Teacher motivation and persistence examines motivation among educators. **Framing the 5 Percent Problem** studies teacher persistence with AI tools, and **Chiu et al.** found need-supportive professional development fosters sustained behavioral engagement in professional learning communities.

- **Cross-cultural motivation of future teachers:** Martínez-Moreno et al. (2026) validated the (D)FIT-Choice scale with 416 student teachers in Switzerland and China, finding Swiss teachers report stronger social utility and intrinsic motivation while Chinese teachers show higher perceived digital competence and enthusiasm for integrating AI — highlighting how cultural and systemic factors shape motivation to shape the future of education with AI.
- **Self-efficacy is the root of teachers' enjoyment of GenAI.** In a PLS-SEM study of 434 in-service teachers, self-efficacy was the model's only exogenous variable and its largest effect was on perceived enjoyment (β = 0.805, f^2 = 1.839), feeding perceived usefulness and ease of use in turn (Guillén-Gámez et al., 2026).

The effort paradox and the vicious cycle of assistance. Zohar, Bloom and Inzlicht (2026) argue that motivation is not simply helped or hindered by AI but redistributed: humans generally take the path of least resistance, yet they also seek effort out — the effort paradox — because effort signals that actions matter and because reward attached to process rather than product increases the tendency to strive and persevere. Two claims follow. First, the effort–meaning relationship is an inverted U, so the motivational target is moderate friction, and the risk of frictionless AI is overshooting into too little. Second, a vicious cycle: as AI replaces effort in a domain, the motivational benefits of effort there erode, which makes users more dependent on AI, which erodes motivation further. They also separate supplement from substitute by developmental stage — learners in earlier stages risk bypassing the experiences that build perseverance, while those with established skills can use AI to save time (Desirable Difficulties, Self-Efficacy).

The literature measures motivation without a theory of it. A scoping review of 156 studies from 2003 to 2025 found 133 (85.3%) were guided by no specific motivational theory, the most common variable was a generalized academic motivation (n = 89), and 88 studies (56.4%) came from one national context (Li et al., 2026).

Motivation also operates upstream of technology perception, not only alongside it. In a 340-student physics sample, utility value predicted perceived usefulness (β = 0.43) and intrinsic value predicted attitude (β = 0.20), while perceived cost lowered ease of use (β = −0.16) and attitude (β = −0.27) with no direct path to intention (Xue, Xu, Qi & Lu (2026)).

Motivational regulation is the thinnest construct in this literature. Across 39 studies, Pan, Abuhassna and Jiang (2026) found autonomous motivation measured in 2 studies, with identified regulation and controlled motivation in 1 each, against 17 studies measuring basic psychological needs and 10 measuring engagement. The authors call that gap the review's central problem, because regulation asks why a student is motivated while need satisfaction asks only whether the setting supported them.

Connections to related concepts

Motivation is the parent construct of Self-Determination Theory, which specifies the psychological needs (autonomy, competence, relatedness) that sustain intrinsic motivation. It connects to Student Experience as the experiential layer of motivated engagement, to Student Engagement as its measurable dimension, and to Affective Computing for the emotional mechanisms that shape motivation. Motivation also connects to Over-Reliance (AI reducing productive struggle), Self-Regulated Learning (motivated learners self-regulate), and Teaching (motivation applies to educators as well as students).

Common Misconceptions

- **"GenAI's motivation effect is a clean, large gain."** A 42-study meta-analysis (56 effect sizes, 6,059 students) found a motivation effect of g = 0.764 (95% CI [0.566, 0.962]) **but with I^2 = 93.7%**. Heterogeneity that high means the pooled figure describes a set of studies that disagree with each other, so it is an average over inconsistent treatments rather than a reproducible effect.
- **"Reducing frustration is the same as sustaining motivation."** A three-arm RCT found a scaffolded tutor and unrestricted ChatGPT **cut frustration equally** (3.21 and 3.13). Two very different designs produced the same affective result, so frustration data cannot distinguish between them.
- **"A motivating design is a good design."** In **222 first-year high-school students**, a teacher-to-teacher dialogue format **raised ARCS motivation more** than the alternative while **not improving overall evaluation**. Motivation moved and judged quality did not.

- How Should We Design and Facilitate Asynchronous Online Courses When AI Can Do the Work?

Self-Efficacy

> **Self-efficacy** — a learner's belief in their capability to successfully perform a task or achieve a goal. Drawing on social cognitive theory (Bandura), self-efficacy shapes motivation, effort, persistence, and learning engagement. In AI in education, self-efficacy matters in two ways: AI tools can build learners' confidence and autonomy (e.g., by providing Feedback and Scaffolding), and learners' AI self-efficacy — their confidence in using AI technologies — influences how effectively they engage with AI, including how AI-related knowledge translates into career-relevant readiness.

Questions to Consider

- Self-efficacy is a belief about your capability — distinct from actual competence. Have you ever been highly capable at something yet doubted yourself, or confidently wrong about something you couldn't do? What does that gap between belief and ability tell you about why self-efficacy matters?
- AI self-efficacy (confidence working with AI) is a separate construct from AI literacy, and research finds literacy translates into readiness only when learners also have confidence. If someone knows *about* AI but doesn't believe they can use it, what happens to that knowledge — and what does that imply for training?
- Research found that using AI to support understanding was fully mediated by academic self-efficacy in its link to performance, while shortcut use predicted worse outcomes partly independent of self-efficacy. Why would the *same* tool build confidence when used one way and fail to when used another?
- The page distinguishes self-efficacy from the everyday word 'confidence.' Before you read, how are they different, and why would a researcher insist on the distinction rather than treating them as the same thing?
- Robotics and embodied learning build confidence by grounding tasks in observable outcomes, and feedback can build learner self-efficacy. Think of a task where you gained real confidence only after seeing a concrete result. What does that say about what kinds of AI learning experiences are most likely to build — rather than merely report — self-efficacy?
- Teacher self-efficacy affects adoption and integration of AI. If a teacher doesn't believe they can use AI effectively, does any amount of AI literacy fix it? What would build a teacher's confidence, and how is that different from giving them more information?

Introduction

Self-efficacy is distinct from actual competence: it is a belief about capability that drives behavior. It is closely related to — and often used interchangeably with — the everyday notion of *confidence* in one's abilities. Self-efficacy connects closely to Motivation, Self-Regulated Learning, and Student Experience. In the AI context, AI self-efficacy (confidence in working with AI) is a distinct construct from AI literacy, and research shows it plays a crucial role in whether learners actually activate and apply AI-related knowledge.

How self-efficacy appears in the knowledge base's research

- **Declines under GenAI-plus-XR studio work:** in a 27-student architectural design studio, teams using a GenAI and multi-user XR pipeline showed larger relative pre–post declines in design self-efficacy confidence (β = −1.675, p = 0.021) and outcome expectancy (β = −2.088, p = 0.002) than teams continuing the normal workflow, with no significant difference in blinded panel ratings of their presentations (Xiao et al., 2026). Tool-rich environments can depress efficacy beliefs even when the work itself is judged equivalent.
- **AI self-efficacy and career readiness:** Research on AI readiness shows that AI self-efficacy moderates the relationship between AI literacy and AI readiness: literacy translates into readiness only when learners have confidence in using AI, and self-efficacy directly predicts career adaptability.
- **Confidence is not always the lever.** A cross-sectional SEM of 502 university faculty found technological self-efficacy a small predictor of AI Well-Being (β = 0.082) while AI literacy dominated (β = 0.713), bounding the claim that confidence gates AI outcomes: for well-being, knowledge outweighed confidence (Liu et al. (2026)).
- **Skills can enable dependency while efficacy buffers it.** Among 478 Israeli undergraduates, the skill dimensions of AI literacy were positively associated with AI dependency (using/understanding AI β = 0.404) while AI self-efficacy was negatively associated (β = −0.132), so literacy training that builds only tool skill may increase reliance (Maizel et al. (2026)).
- **Low confidence routes into heavier AI use, then into lower scores.** In a 153-student proof course, one point higher baseline self-efficacy predicted 39% fewer chatbot messages, and one point lower self-efficacy corresponded to 0.62 fewer exam points through chatbot use (Chen et al. (2026)).
- **Trust as the pivot between literacy and confidence:** Hu (2026) surveyed 450 university students who already use ChatGPT and found an ordered chain rather than two parallel correlates: AI literacy related to Trust in the tool (beta = 0.50), trust to academic self-efficacy (0.48), and self-efficacy to continued use, with the serial indirect effect significant (0.07, 95% CI [0.04, 0.10]). AI anxiety weakened the literacy to trust link (interaction beta = -0.25, simple slopes falling from 0.76 to 0.25 across the anxiety range), so the same knowledge bought less confidence, and reached less use, among more anxious students. Confidence is thus a downstream link in the chain rather than a starting point.

The anxiety route through which AI-assisted practice relates to willingness can reverse rather than fade with confidence: the conditional indirect association fell from 0.142 at low speaking self-efficacy to 0.044 at the mean and −0.054 at high, an effect concentrated in a small upper tail (Wang & Li (2026)). - **Profiles of academic self-efficacy and who reaches for AI:** Suriá-Martínez et al. (2026) ran a latent profile analysis of academic self-efficacy among 102 university students with motor disabilities in Spain and found three profiles (low 29.4%, moderate 41.2%, high 29.4%) whose reported AI use rose stepwise with profile level (means 2.41, 3.56, 4.68; F(2, 99) = 27.84, p < .001, eta squared = .36). Excellence, the planning and goal-setting dimension, was the one most strongly associated with AI use (beta = .47). The authors read this as an equity problem: if confidence tracks with uptake, students with lower self-efficacy may be the least likely to

reach for AI support that could reduce access barriers, so support for academic self-efficacy belongs inside inclusion frameworks. - **AI use patterns and self-efficacy:** Stamatoulis et al. (2026) found that using GenAI to *support understanding* (evaluative integration) was fully mediated by academic self-efficacy in its association with performance — understanding-oriented AI use builds confidence — whereas shortcut use (low-verification uptake) predicted worse outcomes partly independently of self-efficacy. Self-efficacy is thus both a pathway through which productive AI use helps and a factor that shortcut use may fail to build. - **Attribution shapes whether efficacy grows.** Crediting success to the AI rather than to one's own effort constrains self-efficacy growth and reinforces shortcut patterns, so sequencing complex activities into steps where students attribute progress to their own strategies matters more than the tool (Øby, 2026). - **Robotics and hands-on learning:** REMind's robot-mediated role-play built children's self-efficacy in anti-bullying intervention; robotics and embodied learning generally build confidence by grounding tasks in observable outcomes. - **Creative self-efficacy in children:** Niu et al. (2026) report, in a systematic scoping review of 22 primary studies of generative AI with children aged 6 to 15, that gains in creative self-efficacy cluster with divergent thinking and narrative creativity, mostly through text-to-image tools that lower the barrier between idea and artifact. They stop short of claiming efficacy: the designs are heterogeneous, the review performed no critical appraisal, and the corpus is nearly silent on disability, low-connectivity and underserved learners, so creative confidence is an outcome reported to rise rather than one the field has confirmed. - **Teacher self-efficacy:** Teacher AI competency research examines how professional development builds teachers' confidence in using AI, which affects adoption and integration. Ismael, Luo & Li (2026) add quasi-experimental evidence that an AI-supported e-mentoring model raises EFL pre-service teachers' self-efficacy and emotional intelligence during the practicum: the experimental group gained substantially more than controls on both measures, with a large between-group effect and gains across all self-efficacy subdomains — and the authors attribute them to mentoring AI-mediated within structured reflective cycles rather than to the AI alone. - **Feedback and confidence:** AI feedback and tutoring can build learner self-efficacy by providing actionable, supportive feedback. - **Empowerment in AI Problem Solving:** Zhu and Kong (2026) find that students' empowerment in using AI for problem solving mediates the relationship between perceived project-based learning and satisfaction with an AI literacy course. In their SEM analysis of 1,027 students, PBL fostered conditions that empowered students to use AI for problem solving, which in turn drove course satisfaction — evidence that building students' confidence and capability with AI is a key mechanism of effective AI literacy education.

Self-efficacy connects to Motivation, Self-Regulated Learning, Student Experience, AI Literacy, Learner Agency, and Robots in Education. Building self-efficacy is a key mechanism through which AI supports engagement and learning. Self-efficacy is measured almost entirely by self-report, so its associations with observed behavior deserve the usual caution.

- **AIGC self-efficacy as the pivot between tool and learning.** Liang et al. (2026) find that perceived affordances of AI-generated content raise AIGC self-efficacy (beta = 0.583), which then mediates the paths to learning motivation (indirect effect 0.329) and to self-regulated learning (0.145), with the serial path affordance to self-efficacy to motivation to self-AI Regulation in Education also significant (0.173). The contrast that makes the finding useful is that the quality of AI Assessment feedback did *not* predict self-efficacy (beta = 0.131, n.s.) even though it strongly predicted satisfaction — confidence with the tool is built by directing it, not by receiving good output from it.

- **No treatment effect in a semester-long RCT — confidence rose with course time:** in Thoeni and Fryer's (2026) randomized field experiment with 454 undergraduates in a Principles of Marketing course, self-efficacy rose over the semester for all students (time effect $\beta = 0.099$, $p = 0.0009$, Cohen's $f2 = 0.025$). Neither the group effect ($p = 0.1162$) nor the group × time interaction ($p = 0.5306$, $d = 0.023$) was significant, so the RAG chatbot added nothing. Confidence gains in AI-supported courses can track course progression rather than the tool — an attribution risk for a construct the field measures almost entirely by self-report.
- **Confidence can move opposite to behavior.** In competitive programming, students who stopped competing reported *higher* theoretical confidence than their active peers yet showed significantly weaker upsolving and peer-circle habits ($p < .001$), so a self-efficacy signal alone will mislead an early-warning system (Ruhan et al. (2026)).
- **Confidence can rise while the capability behind it declines.** Among university students, frequent generative-AI use raised perceived confidence and efficiency *and* increased technological dependence in the same learners, so a self-efficacy score taken during AI-assisted work can read high at the moment the underlying skill is eroding (Yan et al., 2025).
- **AI use rode with confidence, but confidence did not predict attendance.** In a PLS-SEM survey of 291 Portuguese students, general AI use was positively associated with self-efficacy for independent learning ($\beta = 0.266$, $f^2 = 0.106$). The construct was modeled as a second-order formative composite of Bandura's four sources — mastery experience, vicarious experience, verbal persuasion, and emotional state. Self-efficacy in turn did not predict absenteeism ($\beta = -0.068$, $p = 0.276$), even though AI use was separately associated with higher absenteeism ($\beta = 0.148$, $f^2 = 0.029$). The AI-use → self-efficacy path was significantly stronger among males than females ($\beta = 0.449$ vs. 0.159; $\Delta\beta = -0.289$, $p = 0.013$), under partial measurement invariance (Franco et al. (2026)).
- **Confidence after a structured protocol tracked structure, not dose.** Post-protocol confidence in solving similar problems independently averaged 7.18 on a 1–10 scale ($\sigma = 1.62$, $n = 217$), with institutional means ranging only 6.86 to 7.52 across four campuses. It tracked the perceived benefit of the AI explanation ($r_s = 0.37$) and of replicated practice ($r_s = 0.35$), more weakly prior AI confidence ($r_s = 0.20$), and not usage frequency ($r_s = 0.02$, $p = 0.749$) or self-reported GPA ($r_s = 0.13$, $p = 0.064$) (Paul et al., 2026). That is a mastery route — authored difficulty, then an independent attempt — rather than more time in the tool, a distinction the page lacked. The study measured no learning outcome, so it bounds what students believed.
- **Open-ended AI design tasks sort students by pre-existing confidence.** Zangari et al. (2026) found that performance self-esteem correlated with extroversion ($r = 0.262$, $p < 0.001$) in a course where 345 students each built a conversational agent to teach a peer, and that female students reported significantly lower self-esteem than male peers (Kruskal-Wallis $H(2) = 9.87$, $p < .005$). The design inference the authors draw: open-ended, conversational creative tasks advantage the already-confident, so "open-ended design tasks [should] include sufficient scaffolding to equitably build performance self-esteem across all personality types" — a caution that student-created-artifact assignments can widen, not close, confidence gaps if scaffolding is not deliberate.

- **Self-efficacy interacts with format preference, not just with outcomes.** A counterbalanced within-subject study (97 ninth-graders; content-matched tutor-based vs. paper-based practice of graph interpretation and construction) found tutor-based practice beat paper overall ($t(62.30) = 2.38$, $p = .020$), and — counterintuitively — lower baseline self-efficacy predicted *greater* gains in both formats ($t(98.40) = -2.14$, $p = .035$). The interesting structure is a significant three-way self-efficacy × favorability × format interaction ($t(99.84) = -2.58$, $p = .011$): among low-self-efficacy students, favorability toward the tutor predicts larger gains *specifically in tutor practice*. A sobering null for the assumption that tutor practice is motivationally self-reinforcing: ITS practice did not significantly improve post-training self-efficacy over paper — attributed to the short intervention (two ~40-minute sessions). The practical signal: baseline self-efficacy and technology favorability are cheap, actionable inputs for format assignment; tutor practice capitalizes on existing favorability rather than creating it. (Self-efficacy and favorability shape learning from tutoring systems and paper practice)
- **Knowledge reached intention through trust, anxiety and self-efficacy.** In a PLS-SEM model of 526 design students, perceived AIGC knowledge was positively associated with trust, self-efficacy and usage intention and negatively with anxiety, and trust, anxiety and self-efficacy each carried a significant indirect path from knowledge to intention (Wei et al., 2026). Anxiety sat on the pathway rather than blocking it.
- **"Low writing confidence shows up as a request for help."** It shows up as a request for prose. In an instrumented essay study, the Self-Efficacy for Writing Scale predicted total queries negatively (**-0.258**, SE **0.075**, $p < 0.001$), and the association ran through Translating (**-0.949**) and Reviewing (**-0.588**) rather than Planning (**-0.204**) or whole-essay delegation (**-0.016**). Students who doubted their writing asked the model to produce and correct text; they did not ask it what to argue. Self-efficacy predicted reliance, and the reliance took a specific shape.

Confidence does not protect a learner from trusting a tool too much. Among 300 university students, Kim, Kim and Zhang (2026) found academic self-efficacy associated with AI overtrust ($r = 0.230$) and predicting it at $B = 0.3901$ (95% CI [0.2190, 0.5612]) in a serial mediation model, reversing the authors' hypothesis. The productive version of confidence is confidence about one's own judgment, which is what a high overtrust score says is missing.

- **Confidence reaches adoption partly through literacy.** Belief to behavior: how AI self-efficacy shapes AI acceptance through AI literacy tested a sequence on 622 undergraduates in Türkiye. AI self-efficacy predicted AI acceptance ($B = 0.43$, $R^2 = 0.29$), and AI literacy carried part of that link (indirect $B = 0.15$, 95% CI [0.12, 0.19]) without absorbing it all. Confidence also has to be accounted for as a predictor of uptake, not only of capability. The design is cross-sectional with no demographic controls, so direction and mediated share are associations rather than effects.
- **Necessary for usefulness, not merely correlated with it.** Chu and Liu (2026) placed AI self-efficacy in front of the two acceptance beliefs for 405 design graduate students and found it the strongest antecedent of both: $\beta = 0.458$ on perceived usefulness and $\beta = 0.394$ on perceived ease of use. Their necessary condition analysis adds a stronger form of claim than the path above. Efficacy was the only condition identified as necessary for perceived usefulness ($d = 0.125$, $p = 0.015$). Usefulness at 80%, 90% and 100% of its scale required efficacy at 10.0%, 30.0% and

50.0%. Confidence therefore sits as a floor under the instrumental judgment rather than as one contributor among several. The design is cross-sectional and the model explains $R^2 = 0.150$ of intention, so treat the thresholds as within-sample.

- **Behavioral traces can carry the signal, but the labels set the ceiling.** A two-university pipeline detected low self-efficacy from interaction traces; survey-occasion labels beat a mid-term split, and the MSLQ subscale alone labeled as well as the full instrument (Somny, Chouati & Lefevre, 2026).

Common Misconceptions

- **"Students who lack confidence avoid AI."** The opposite pattern appears: in a **153-student proof course**, one point higher baseline self-efficacy predicted **39% fewer chatbot messages**. Low confidence routed into **heavier** AI use — the students most in need of practice were the ones most likely to offload it.
- **"More AI use with low confidence is a harmless coping strategy."** The same finding links that routing to **lower scores**, so the coping pattern has a measurable cost rather than being neutral choice.
- **"Literacy alone builds confidence."** Hu (2026) surveyed **450 university students** who already use ChatGPT and finds **trust as the pivot between literacy and confidence**. The path runs through trust, so raising literacy without addressing trust leaves the mechanism untouched.
- **"Self-efficacy profiles are uniform in a disabled population."** A latent profile analysis of **102 university students with motor disabilities** in Spain found **three profiles**, with the low group at **29.4%** and the remainder split across moderate and higher profiles. Treating the group as one population averages over distinct motivational states.

Self-Directed Learning

> **Self-directed learning (SDL)** — the process by which learners take initiative and responsibility for diagnosing their own learning needs, setting goals, identifying resources, choosing and implementing strategies, and evaluating outcomes, often with limited external structure. In the AI era, SDL is both a key outcome (does AI use support or erode learners' capacity to direct their own learning?) and a vulnerability (the convenience of generative AI can undermine the very autonomy and Self-Efficacy SDL requires).

Questions to Consider

- Self-directed learning means diagnosing your own needs, setting goals, and evaluating outcomes with limited external structure. Before you read, how comfortable are you actually directing your own learning — and has an AI tool ever made you *less* able to, without you noticing?
- The page frames SDL as both a hoped-for outcome and a vulnerability: generative AI's convenience can erode the very autonomy and self-efficacy SDL requires. Why would a tool that gives you instant answers make it *harder* to direct your own learning later?
- Thoughtless use of GenAI — adopting outputs without critical evaluation — was found to harm SDL both directly and by eroding self-efficacy and motivation. Can you recall a time you accepted an AI answer without evaluating it? What, if anything, did that cost you?
- SDL and self-regulated learning (SRL) are closely related but distinct: SRL concerns in-the-moment AI Regulation in Education of learning, while SDL concerns overarching responsibility across time. Where do you see the boundary between 'managing this task' and 'directing my own learning' in your own practice?
- The harm from thoughtless AI use hit motivation harder for some students and self-efficacy harder for others. If the erosion of these psychological resources is uneven across learners, what equity concern does that raise about who loses the most from AI convenience?
- Set a goal before you read: name one learning goal you're currently pursuing mostly on your own, and one way an AI tool helps you toward it and one way it might be quietly taking the directing away from you.

Introduction

Self-directed learning is a close neighbor of self-regulated learning (SRL), not a synonym. While SRL emphasizes the in-the-moment cognitive, motivational, and behavioral regulation of learning (planning, monitoring, controlling, reflecting), SDL emphasizes the learner's overarching responsibility for the direction and management of their own learning across time, often in informal or self-chosen contexts. SDL is foundational to adult learning and lifelong learning, and is a prominent theory in distance and online education, where learners must sustain autonomy without scheduled class time. SDL is also increasingly *tractable* to empirical study: analyzing the clickstreams of 315 online learners who built 822 models in VERA, An, Hammock & Goel (2025) identified three behavioral signatures of self-direction — Observation,

Construction, and Exploration. They also found learners progressing from hands-on construction toward fuller, hypothesis-driven Exploration while Observation persists across all phases, showing that the degree and kind of autonomy learners exercise in an unstructured online task can be distinguished from their trace data alone.

How generative AI reshapes self-directed learning

The knowledge base's research documents both sides of the GenAI–SDL relationship.

- **AI can support SDL.** AI and lifelong learning and self-directed growth with GenAI + learning analytics show that AI tools can scaffold independent inquiry, provide on-demand resources, and personalize learning paths in ways that strengthen learner autonomy. Meta-analytic evidence on generative AI educational outcomes and conversational AI in informal learning suggest positive potential when AI is used as a resource the learner directs.
- **Learners want a thinking partner, not an oracle.** Interviewed adult learners wanted AI to prompt reflection and verify rather than supply answers, and to leave them in control of the learning path rather than prescribe it (Kim et al. (2026)).
- **Delegating goal choice is not the same as supporting it.** The page treats setting the goal as the learner's core act, and the benchmark evidence says models do it differently. Against 175 humans, GPT-5, Claude Sonnet 4.5 and Qwen3 32B re-selected the previous goal on 0.93, 0.93 and 0.94 of trials, against 0.54 ± 0.18 for people. Goal entropy was 0.12 to 0.20 against 1.67 ± 0.14, and chain-of-thought and persona prompts did not close the gap. A system that proposes what to learn next reproduces a narrower search than the learner it stands in for (Molinaro et al., 2026).
- **Thoughtless use undermines SDL.** Zhao & Gu (2026) show that the **thoughtless use of GenAI** — adopting AI outputs without critical evaluation — significantly harms undergraduates' SDL both directly and through erosion of Self-Efficacy and Motivation (the model explained 75.3% of SDL variance; TUGA $\beta = -0.42$). The negative effect on motivation was stronger for male students and on self-efficacy stronger for female students. This connects to the broader over-reliance risk documented in the knowledge base.
- **Cognitive offloading and delegation.** Andragogy and cognitive delegation and learning by chatting with GenAI examine how learners may delegate cognitive work to AI in ways that bypass the effortful processing SDL requires — a failure mode of otherwise autonomy-supportive tools. Scaffolding critical thinking with GenAI and test-driven AI-assisted learning model more productive designs.

The SDL–SRL distinction in practice

Because SDL emphasizes learner-initiated direction, interventions to protect it focus on preserving Learner Agency and self-efficacy rather than merely regulating moment-to-moment behavior. The evidence that thoughtless AI use erodes motivation and self-efficacy — the psychological resources SDL depends on — suggests that promoting responsible AI use is not just an integrity issue but a developmental one: protecting students' capacity to direct their own learning.

AI Extraction Scaffolding Research-Based Learning

- **AI extraction as a scaffold for research-based learning.** An and colleagues (2026) design an AI-powered information extraction system that converts research publications into structured, traceable datasets to support undergraduate thesis completion in STEM, positioned as an **epistemic scaffold** that enables inspection of evidence-claim relationships while reducing low-level data-handling demands. In a 20-student mixed-methods pilot across 80 documents, students extracted over 90% of targeted parameters, self-reported literature-review time dropped ~65%, and their ability to identify influential variables rose 50% — supporting the idea that AI can rebalance cognitive load toward higher-order, self-directed research reasoning rather than routine summarization.

Common Misconceptions

“Self-directed learning and self-regulated learning are the same construct.” They operate at different timescales: SRL concerns in-the-moment regulation of learning, while SDL concerns overarching responsibility across time — choosing what to learn, setting the goal, and holding the direction over months. An intervention that improves moment-to-moment regulation need not produce a self-directed learner, and a student can be self-directed across a program while regulating poorly within a session.

“AI makes self-directed learning easier because it supplies structure.” It can remove the exercise of the skill. Zhao and Gu (2026) show that **thoughtless use of GenAI — adopting outputs without critical evaluation — significantly undermines SDL**. Directing one’s own learning is practiced by making the decisions GenAI can now make for you, so an assistant that always supplies direction supplies it in place of the competence.

“Non-use of AI indicates a lack of access.” Among students who do not use it, the stated reason is often a positive educational choice — wanting to do the work themselves — rather than a barrier. Reading non-use as a deficit misdescribes a position that is, in the Student Experience evidence, reasoned.

“Self-direction means working alone.” It means owning the direction, which can be exercised in a highly supported environment. The distinguishing feature is who sets and adjusts the goal, not whether help is available.

Implications for Practice

For instructors

- Distinguish what you are developing: in-session regulation or across-time ownership. They need different designs, and improving one does not produce the other.
- Protect the decisions that constitute self-direction — what to learn, how to judge progress, when to change course — even where AI could make them. Delegating them removes the practice.
- Teach evaluation alongside use, since thoughtless adoption of outputs is the documented mechanism by which GenAI undermines SDL.

For developers

- Make the learner's decisions visible and revisable rather than setting them by default. A system that always supplies direction supplies it in place of the competence being developed.
- Build reflection checkpoints where the learner states their goal and their evidence, so direction remains theirs.

For researchers

- Report which construct an intervention targeted; SDL and SRL outcomes should not be used interchangeably.

Metacognition

> Metacognition — thinking about one's own thinking — is both a target of AI education research (can AI tools develop students' metacognitive skills?) and a risk factor (AI completing tasks may suppress metacognitive practice).(The Evidence Base on AI in K-12: A 2026 Review)(Designing a mobile chatbot-based learning journaling system for intrinsic motivation and engagement)

Questions to Consider

- 'Metacognition' is thinking about your own thinking — knowing what you know, monitoring yourself, and adjusting your strategies. When you study or solve a problem, how aware are you in the moment of whether you actually understand versus just recognizing the material?
- A striking finding: students who used AI essay assistance were often unable to recall quotes from their own essays, because they hadn't engaged with the content during production. When a tool produces the output, what practice is the learner losing — and is that practice important?
- The page frames metacognition as both a target (can AI build it?) and a risk (can AI suppress it?). Could the same AI tool either strengthen or weaken a learner's metacognition depending on how it's designed or used? What determines which way it goes?
- Structured prompts that ask students to self-explain, evaluate strategies, or identify gaps preserve metacognitive demand, while AI that simply completes tasks displaces it. If you were designing an AI study tool, what would you build so that it invites reflection instead of replacing it?
- The page finds that whether AI use is metacognitively rich depends on the learner's motivation and stance as much as on the technology. Have you ever used a tool in a shallow way and then realized you learned nothing — and what was different about times you used it deeply?

Introduction

Metacognition in education refers to learners' awareness, monitoring, and AI Regulation in Education of their own cognitive processes:

- **Metacognitive knowledge:** Understanding what one knows, what strategies are available, and when to deploy them
- **Metacognitive regulation:** Planning, monitoring, and evaluating one's own learning in real time

Within Self-Regulated Learning frameworks, metacognition is the central mechanism that enables learners to adapt strategies, recognize confusion, and seek help appropriately.(Designing a mobile chatbot-based learning journaling system for intrinsic motivation and engagement)

Metacognition is not the same construct as Reflection, and the two are often conflated. Monitoring is a judgment a learner makes about their own state, and it can happen with no record at all. Reflection is the deliberate, documented examination of a completed attempt, and what it produces is a text that can be reviewed or assessed. Keeping them apart matters most when AI is involved: a monitoring judgment is hard to hand over, while a reflection artifact can be produced by a model.

How learners actually deploy metacognition around AI is shaped by more than the tool itself: Cui et al. find that student motivation and the interaction role they adopt shape their metacognitive engagement with GenAI — meaning whether AI use is metacognitively rich depends on the learner's stance as much as on the technology. Miles, Haber-Curran and Arar (2026) add the AI interaction itself as an object of that reflection: the closing step of their Prompt Literacy Cycle asks learners to examine what the process revealed about how prompts function and what assumptions shaped the response, and they make reflection and revision the phase in which authorship and critical judgment develop.

A more fundamental role for metacognition appears when the locus of coordination shifts from teacher to learner. Dang, Hong, Doyle and Nguyen (2026) argue in their Human-AI Collaboration Competency (HACC) framework that the integrative work Technological Pedagogical Content Knowledge (TPACK) assigns to pedagogy passes, once the actor is the learner, to the learner's own metacognition — the competency that lets students direct the collaboration, calibrate their reliance on AI, and remain the authors of their learning. They treat metacognitive competency as the mechanism through which learner agency is enacted, deliberately excluding agency as a separate component and reading it instead as the emergent quality of coordinating domain, AI, and metacognitive competency. Their Epistemic Network Analysis of interviews with 24 higher education educators found metacognitive talk rising with role level — senior educators connected it to domain, AI, and learning with AI — which the authors read as educators with broader curricular responsibility seeing students' persistent difficulties as regulatory rather than technical.

How AI Tools Affect Metacognition

The Suppression Risk (Stanford SCALE, 2026)

When AI completes reasoning tasks for students — solving math problems, writing essays, generating code — the student loses practice in monitoring their own understanding and selecting strategies.(The Evidence Base on AI in K-12: A 2026 Review)

Reliance is not failure: Du and Yuan (2026) judge AI-mediated learning by six diagnostic criteria — contestability, recoverability, transfer, traceability, distributed responsibility and epistemic plurality — and distinguish instrumental assistance, which helps produce output, from judgment-bearing assistance, which supplies the standards by which output is judged. **Naming the governance question.** Lin and Chang (2026) propose **metacognitive ownership** — the learner's governance of the standards, evaluative judgments and actions an AI contributes to — separating standards appropriation, monitoring-judgment governance and control authorization, and requiring a realistic opportunity to act differently.

Key findings: - **Kosmyna et al. (2025):** Students who used AI essay assistance were **83% unable to recall quotes** from their own essays, vs. 11% for non-AI users — indicating they did not engage with the content during production. - **Stadler et al. (2024):** General-purpose AI reduced cognitive load but produced **lower-quality reasoning** vs. traditional search, suggesting metacognitive engagement was displaced. - **Lehmann et al. (2025):** General AI for programming harmed understanding for low-Prior Knowledge students — the students most in need of metacognitive scaffolding received answers instead. - **Metacognitive laziness.** The field names a distinct failure mode in which learners abdicate their metacognitive responsibilities to the tool — adopting the term *metacognitive laziness* for the resulting illusion of competence, and warning that its cognitive risks fall hardest on novices and weaker self-regulators (Lodge & Loble (2026)).

Fluency is why the loss goes unnoticed. Learners judge their learning partly from how easily material is processed, and Bjork et al. (2013) show that fluency cues lead people to overestimate their understanding when content feels easy; fluent AI-generated text supplies that feeling whether or not comprehension followed, creating the conditions for a manufactured illusion of competence. Generativism treats this as the reason adaptive metacognition cannot be assumed: the learner has to ask whether ease of reading reflects understanding rather than reading the ease as the answer.

Awareness does not guarantee that completion stops. Jia (2026) names *metacognitively discordant completion*: a learner who invested real effort, holds a formed first-person verdict that understanding has not arrived, and releases the work anyway — the case the fluency-illusion and withdrawn-effort accounts both assume away.

Learners are also miscalibrated about AI's costs: participants predicted independent times accurately but underestimated AI-assisted time, and reported lower effort (0.61 points on NASA-TLX) while AI sped up only three of 24 tasks — a bias absent when the imagined helper was another person (Yu et al. (2026)).

The cost appears bounded rather than global: offloading degrades the specific skill practiced, not the underlying domain-general abilities, and surfaces on withdrawal: an endoscopy study found adenoma detection fall from 28.4% to 22.4% when the AI was unavailable, leaving source-monitoring (telling an AI's reasoning from one's own) an open metacognitive risk (Cash et al. (2026)).

The Augmentation Opportunity (Scheu et al., 2026)

When AI is designed to support reflection rather than replace it, metacognition can be strengthened:

- **Learning journals** are a classic metacognitive practice: by reflecting on learning processes, students increase awareness of their cognition
- **Structured prompts** that ask students to self-explain, evaluate strategies, or identify knowledge gaps preserve metacognitive demand. CoMeT (Hou et al. 2026) gives that phrase a definition and an empirical warrant: it treats metacognitive demand as a quantity distinct from cognitive load — what the learner must decide, state, or judge before help arrives, not simply what remains when help is withheld — and held it statistically equivalent to a tutor that withheld answers by design ($p_{TOST} = .004$) while its own support escalated and faded one rung at a time. Fading held when the learner's turn was aimed at the decision under support: turns aimed elsewhere drew a later concession 40.3% of the time against 28.8% for aimed turns, an 11.5-point difference, so what a tutor must read for is where the learner's attention sits rather than how much effort the turn displays.
- **Assign an AI-use level per task.** HAIML pairs its three layers with Four AI Use Levels — from no AI use, through brainstorming, to AI collaboration and AI-integrated creation with output evaluation — so an instructor sets the level for a task and keeps metacognitive reflection central at every level (Reardon, 2026).
- The **example-based course** in Scheu et al.'s chatbot increased **perceived competence** (a metacognitive Self-Assessment) even when the Large Language Models (LLMs) assistant alone did not

- **An emerging framing puts the system, not just the individual, in the loop.** A bibliometric–systematic review of 135 STEM-classroom studies (24 core studies) finds a posthumanist framing emerging that positions AI as a co-regulator of learning, shifting the unit of analysis from individual reflection to system-level AI Regulation in Education and distributed cognition (Tsakeni et al. (2025)).

At synthesis scale the pattern holds, and it thins as measurement sharpens. A three-level meta-analysis of 54 (quasi-)experimental studies (121 effect sizes, 7,431 learners) put AI's effect on metacognition at g = 0.624 (95% CI [0.431, 0.817]), with 107 of 121 effects positive and gains rising with exposure from g = 0.381 under a week to g = 1.638 at 15 to 20 weeks (Li et al. (2026)). Measurement source was the decisive moderator: self-report g = 0.776, behavioral observation g = 0.514, and accuracy ratings, the gap between judged and actual performance, g = 0.035 and non-significant. The gain is largest where it is easiest to claim and near zero where monitoring is scored against performance, which is the self-report problem the studies above keep running into.

Metacognition is among the least-studied outcomes. In a scoping review of 394 GenAI higher-education studies, metacognition and self-regulated learning were among the outcomes targeted least, alongside Ethics and Creativity (Lin et al. (2026)).

- **Surfacing interaction patterns that learners cannot see.** Kuang, Li and Weng (2026) tracked eye movements, note-taking and speech while 22 interpreting trainees worked with a speech-recognition and machine-translation system, and found that the way students divided attention between AI output and their own notes was invisible to them: 58.3% changed profile between task stages, and the heaviest readers of AI output scored lowest on delivery fluency and target language quality. The pedagogical consequence is that reflection has to be scaffolded by external evidence, because a learner's strategy is not introspectable — the authors argue for guiding students to describe and evaluate why they worked a given way at each stage.
- **Process evidence is channel-conditional.** In 79 undergraduates working with generative AI, higher-depth monitoring and planning appeared more often in think-aloud units while higher-depth regulation appeared more often in interaction logs, so one record alone understates some processes (Li and Liu (2026)).
- **Reflective practices can emerge from ordinary subject-matter use.** Across eight Danish upper secondary schools, students working with Generative AI as a cognitive partner developed four practices — explanation, creation, inspiration, and improvement, unfolding into eleven processes — in which reflection appeared in both disciplinary and process registers, though each practice could equally serve substitution (Dalsgaard & Prilop, 2026).
- **A reflective scaffold can habituate and replace the self-monitoring it protects.** de Jong (2026) warns that repeated prompts to reflect may wear off through habituation — much as repeated warnings are dismissed automatically — so a professional who reflects only when the system asks may end with neither the tool nor the self-monitoring habit; the paper argues reflective prompts should be treated as a fading skill-building intervention and tested for whether users reflect without them.
- **A selective gain: metacognitive knowledge without planning and monitoring.** Wang et al. (2026) split 68 preservice teachers into a group that explained the flipped classroom to a

generative AI novice learner (n=33) and a group that questioned a generative AI teacher (n=35). The novice-learner group scored higher on metacognitive knowledge and learning strategies ($p < 0.001$, Cohen's $d = 0.41$) but not on planning and monitoring (M = 4.01 vs. 3.78, $p = 0.062$), even though the same group's explanation and application scores rose ($r = 0.474$ and $r = 0.642$) while factual recall did not separate the groups ($p = 0.416$). The split follows the two components in the Introduction: explaining to someone who asks back built declarative awareness of what one knows, but nothing in the design made the learner set a route or check progress, which the authors attribute to task design and cognitive load rather than to the role itself. Learning by Teaching with AI is therefore a lever on metacognitive knowledge, not automatically on regulation, and the authors recommend adding explicit planning prompts and progress feedback.

- **Think Aloud supports early awareness but not deep evaluation.** Karaki and Baroudi (2026) ran a mixed-methods action-research study with 44 first-year entrepreneurship students using the Think Aloud method during AI-supported coursework. Think Aloud made students' prompt construction, verification practices, and ethical decision-making more visible, but critical evaluation of AI outputs "often remained at a surface level, particularly among students requiring additional support" — students spotted generic or misaligned responses yet kept relying on them heavily. Self-reported metacognitive awareness was the highest of three surveyed constructs (M = 3.79), but the single post-intervention survey cannot separate perception from change. The authors' conclusion — Think Aloud is not a stand-alone solution and must be combined with explicit instruction in AI literacy, prompt construction, and verification strategies — extends the process-evidence line above from *what records capture* to *what vocalization alone changes*.
- **Prior metacognitive training gates the benefit of an AI reflection partner.** In a 2 × 2 experiment with 60 pre-service teachers, Zhang et al. (2026) found a significant metacognition × tool interaction: an AI Socratic partner beat traditional digital tools by 0.56 points only after training, with no advantage without it ($\Delta M = -0.03$).

Braun (2026) gives the suppression account a preregistered causal test (N = 317) against worksheets. Disorganization rose by 0.84 (95% credible interval 0.47 to 1.21) and was the clearest effect in the model, while deep processing fell through a chain running from offloading to critical thinking rather than directly. The author names the state cognitive dormancy, in which monitoring and strategy selection go quiet while processing continues, and locates its cause in the affordances of the environment rather than in the learner.

Monitoring changes the route more than it blocks the path. Guo and Dong (2026) split 600 undergraduates by a monitoring item and estimated each group separately: load predicted cognitive offloading at $\beta = 0.844$ for low monitors and $\beta = 0.840$ for high, effectively the same. Offloading predicted overreliance at 0.396 and 0.506, and the direct load path ran 0.560 and 0.419. Dependence among stronger monitors therefore traveled more through offloading and less directly. These are separate models, not a formal multi-group test.

When monitoring is skipped

Xiao et al. (2026) turned the suppression risk into a measured quantity across four experiments with 728 adults. Higher AI assistance raised task-level disengagement to 4.82 from 3.96 ($d = 0.67$), and offloading carried 58.0% of the effect (indirect 0.51, 95% CI [0.32, 0.72]). Expert raters then scored the delegated

proposals lower: quality fell from 4.78 to 3.95 (d = 0.75), with 57.8% of that drop running through disengagement (indirect -0.48, 95% CI [-0.68, -0.30]).

The cost is conditional. Task complexity strengthened that path (index -0.39, 95% CI [-0.62, -0.16]) while AI literacy weakened it (index 0.30, 95% CI [0.09, 0.52]). So monitoring is not only a capacity that predicts better use; skipping it is a step whose absence is visible in output quality through an offloading route. Two limits bound the claim. The AI was a researcher-scripted response bank, not a live model, and occupation and student status went unreported, so this is neither a classroom nor a workplace study.

The Engagement–Motivation Distinction

Scheu et al. (2026) found a critical split:

Dimension	LLM Assistant Effect	Course Effect
Intrinsic motivation (willingness to engage)	**No effect**	**Positive**
Behavioral engagement (amount written)	**Increasing over time** (feedback loop)	**Constant positive**

This suggests that **metacognitive support and Motivation are not identical**. The LLM assistant's Scaffolding of journal entries increased how much students wrote (behavioral engagement) but did not make them *want* to write more (intrinsic motivation).(Designing a mobile chatbot-based learning journaling system for intrinsic motivation and engagement)

The Beliefs-vs-Experiences Distinction

Guo & Ye (2026) offer a theoretically sharper account of how metacognition governs strategy selection, distinguishing two components that operate in different phases:

- **Metacognitive beliefs** — stable, self-referential self-conceptions stored in long-term memory (e.g., beliefs about one's memory capability, or the reliability of a tool). These anchor strategy choices *before* task initiation.
- **Metacognitive experiences** — dynamic, task-specific feelings (perceived difficulty, confidence, mental workload) that drive belief *updating* during task execution.

This distinction yields the principle of **timing-component matching**: feedback that targets beliefs (e.g., comparative rankings) is most effective in the pre-task preparation phase, whereas feedback that targets experiences (e.g., immediate correctness indicators) is most effective during task execution. Abstract ranking feedback can become separated from — or overridden by — the task-specific experiences that dominate immediate decision-making, explaining why some feedback interventions fail to change behavior. This gives educators a phase-contingent rationale for designing metacognitive scaffolds around AI tools: calibrate beliefs before use, provide immediate task-specific feedback during use.

External support can also step in front of the judgment entirely. Iqbal et al. (2026) had 87 EFL students revise an essay with ChatGPT 4.0, an experienced academic writing instructor, or no support, and reconstructed the strategies students used from clickstream, keystroke and mouse traces. What they chose was strongly associated with the support available (Cramér's V = 0.668), but not with metacognitive

judgment accuracy ($H(3) = 4.995$, $p = 0.172$), which showed a marginal link only in the no-support condition ($p = 0.0460$). No revision strategy was associated with essay-score change ($p = 0.273$), yet the GenAI group improved significantly more than the other two ($H(2) = 16.591$, $p = 0.00025$, $\eta^2 = 0.174$), so the stronger essays did not come from better self-regulation. When a capable partner can supply the next move, metacognitive judgment stops being what selects it, and the strategy-choice account above describes the unaided learner more than the supported one. The authors' practical reading is to aim AI assistance at prompting reflection on writing strategies rather than at supplying direct help.

Calibration is trainable: prediction + feedback

Ngai & Gilbert (2026) provide direct causal evidence that metacognitive calibration is a *trainable* skill. In two preregistered experiments (N=164, N=416), **just five practice trials pairing a performance prediction with veridical feedback** improved calibration and reduced bias. A four-group additive design isolated the causal component: **making predictions alone was ineffective; adding performance feedback drove the improvement; explicitly labeling over-/underconfidence added nothing further**. Critically, the improvement acted on *absolute* calibration — raising confidence in the underconfident and lowering it in the overconfident — so it corrected miscalibration in both directions rather than shifting everyone one way (which is why signed/directional effects were null). This strengthens the "experiences not beliefs" account above and shows the *minimum viable metacognitive training*: prediction + immediate, task-specific feedback.

- **A brief reflection prompt sharpens monitoring during AI-supported decisions.** Ren (2026) added three reflection prompts before finalizing answers in a three-condition experiment with 342 undergraduates: acceptance of incorrect ChatGPT advice fell from 62.4% to 39.7% (*OR* = 0.40) and awareness calibration rose (0.59 vs. 0.41), while recommendation accuracy and alignment with correct advice stayed high. Reflection made reliance more discriminative rather than uniformly defensive, which supports treating reliance as a monitoring problem rather than a question of how much AI is used.
- **Nest prompting inside a metacognitive cycle.** The IDEA framework sequences GenAI use as Intent, Deconstruction, Expression, and Adaptation, making prompting one step in planning and monitoring rather than a stand-alone skill; students taught it produced higher-quality prompts than peers taught Role–Task–Context–Format prompting in all five task categories (Wang et al., 2026).

Implications for Tool Design

1. **Preserve the "friction" of thinking:** If AI writes the reflection, the student does not build metacognitive skill. Journaling assistants should scaffold, not author.
2. **Model metacognitive language:** The example-based course worked partly because it exposed students to proficient models' metacognitive self-talk.
3. **Separate support for motivation vs. skill:** Metacognitive skill development (course-structured) and productivity enhancement (AI-assisted) may require different design strategies.
4. **Name the target as onloading, and ration the help.** A metacognitive approach to learning and performance in human-AI interaction separates cognitive offloading, which stays under metacognitive control, from *metacognitive* offloading, where planning, monitoring, evaluation and

judgment calibration are handed over. Their design target is metacognitive onloading: scaffolds that make the learner, not the AI, set goals, anticipate difficulty and judge strategies, placed within a prompt, across a task, and fading over time. The help rule is minimum-necessary: a hint or diagnostic question first, with deeper assistance unlocked only after the learner asks, monitors or chooses a direction. The paper is conceptual and its authors note that no validated measure of either construct yet exists.

AI may alter the **metacognitive threshold** for deciding one knows enough to answer: Marcoccia et al. (2026) found that mere access to AI advice suppressed people's willingness to suspend judgment under uncertainty, even with wrong advice and accuracy incentives — an effect that survived unsolicited AI output and monetary stakes.

Proactive agentic AI can displace the learner's own metacognitive loop: Woollaston et al. (2026) argue that when agents pre-fetch, initiate, and self-correct, the agent's planning, monitoring, and evaluation replace the learner's, removing the retrieval practice and self-monitoring that desirable difficulties and metacognitive training depend on.

- **Mistake-based Pedagogies and Teaching Strategies as metacognitive training:** Hosseini (2026) shows that deliberately exposing students to AI-generated errors in a database design course activates metacognitive monitoring — students inspected outputs, identified errors, and revised designs rather than accepting AI output at face value. Self-reported AI literacy correlated weakly and negatively with objective competency (r=−0.39), a calibration gap the critique-refinement cycle is designed to narrow.
- **Productive failure engages metacognitive monitoring.** Kim et al. (2026) show productive-failure-based learning activates reflection on one's own attempts; clue-before-correction tasks require learners to diagnose and correct their own errors — a metacognitive activity where AI gives clues rather than answers.
- **Self-regulation buffers offloading harm but cannot cancel it.** Chen (2026) shows that metacognitive regulation (self-regulated writing) attenuates the negative association between deep cognitive offloading and independent no-AI outcomes in GenAI-assisted writing (interaction B = 0.22), but does not eliminate it — a bounded-support condition pairing delegation limits with compulsory reflection about how AI suggestions were accepted/rejected produced the strongest independent performance.
- **Explanation-seeking depth predicts task quality, not recall.** Tsiligkiris (2026) shows explanation-seeking prompts (depth) in LLM interaction predict task quality but not immediate recall, interpreting the dissociation via elaboration (comprehension) vs. retrieval practice (consolidation) — and suggesting explanation-seeking correlates with metacognitive monitoring, though retrieval demands must be added for durable retention.
- **Self-reported metacognition is a weak proxy for regulation *with* an LLM.** Clerc et al. (2026) gave 116 middle-school students a two-hour AI literacy workshop and then measured their LLM interaction during science problems: trained students accepted underspecified prompts less often (51.5% vs. 66.7%), asked follow-up questions after a weak response far more often (59.2% vs. 27.9%, d = 0.80) and judged answer correctness more sensitively to prompt quality (interaction OR = 2.52). Neither a general metacognitive-awareness scale (Jr. MAI) nor GenAI self-reports

predicted those behaviors or final performance (r = .04 and r = .01) — monitoring and control during generative AI use is task-specific, and observable behavior carries more information than the self-report instruments built to capture it.

- **Automated scoring reached the performance phase, not the planning that precedes it.** Chen and Liu (2026) gave 46 interpreting students 14 weeks of weekly automated scoring with a returned score, marked errors, and a reference rendition: the automated group gained more overall (d = 1.03). Only monitoring during practice correlated with score gains (r = 0.42), while pre-learning planning sat near the scale midpoint (M = 3.01). Evaluation and reflection carried the second-highest mean (3.87 of 5) yet showed a near-zero link to gains (r = 0.10), so a high reflection score should not be read as productive reflection.
- **Verification literacy pays off only through metacognitive self-regulation.** Davor, Larbi and Boateng (2026) surveyed 533 university students and found that AI verification literacy had no direct association with critical thinking or technical Problem Solving; it mattered only indirectly, through metacognitive self-regulation (a full mediation pattern). Cognitive offloading tendency ran the other way, predicting lower self-regulation (-.294) along with lower critical thinking (-.240) and problem-solving (-.312).
- **Reflection rose with AI access, and it fed reasoning rather than test scores.** Melanou, Beege and Kimmig (2026) followed three classes (N = 87) across a nine-week course, measuring at three points. Knowledge improved in all conditions with no advantage for either AI condition and no Matthew effect (BF01 = 8.70), but reflective use (checking sources and verifying AI output before adopting it) was far higher in the AI condition than the control group (M = 3.72 vs. 2.82, $F(1, 40) = 20.21$, $p < 0.001$) and predicted critical thinking ($\beta = 0.43$, $p < 0.001$, $R^2 = 0.183$) while predicting no knowledge gain. Reflection appeared from tool access alone rather than from scaffolding, and because its payoff lands in reasoning, a knowledge test will not register the metacognitive benefit of an AI-supported course.
- **Inside a metacognitive self-report instrument, awareness outpredicts the rest.** Alatoai and Alshahri (2026) validated a 45-item measure of AI-supported STEM learning with 649 Saudi secondary students (CFI = 0.983, RMSEA = 0.019; subscale ω = 0.888–0.905) and used it to rank the components. The four dimensions explained 68% of the variance in self-regulated learning scores, with AI-based metacognitive awareness strongest ($\beta = 0.38$, $p < 0.001$), cognitive transfer and adaptability next ($\beta = 0.29$, $p = 0.008$), and creative and critical AI-STEM reasoning not significant ($\beta = 0.14$, $p = 0.135$). Awareness is the component that carries adaptive performance, the authors advise reporting subscales separately rather than one global score, and they reserve higher-order reasoning for reasoning-quality tasks; the measure is nonetheless self-report, so like the workshop study above it captures perceived capability rather than observed strategy use.
- **The evaluator's own monitoring is metacognitive work too.** Hoppe, Loibl and Leuders (2026) argue that an AI-generated diagnostic inference is not raw evidence but an interpretation already made, so teachers must integrate it with their own observations in a process they call *meta-diagnosis*, deciding deliberately whether to accept, reject, or modify it. That places a second metacognitive loop beside the learner's: not only how the student regulates thinking with AI, but how the teacher evaluates what the system claims about that thinking.

Common Misconceptions

- **“AI assistance leaves the underlying ability intact.”** Students who used AI essay assistance were **83% unable to recall quotes from their own essays, against 11% for non-AI users**, indicating **they did not engage with the content during production**. The production process is where the engagement happens, and bypassing it shows up later.
- **“Offloading degrades everything.”** The cost appears **bounded rather than global**: offloading degrades **the specific skill practiced, not the underlying domain-general abilities**, and surfaces on **with**-something transfer tests. The localisation matters, because it says what to protect rather than warning about general decline.
- **“Ability to produce implies ability to retain.”** The 83% versus 11% recall gap is the direct counterexample: output was produced in both conditions and the memory trace differed enormously.

Reflection

> **Reflection** — the deliberate, retrospective examination of one's own experience, work or reasoning, externalized in written, spoken or recorded form so that it can be revisited, shared or assessed. Its nearest neighbour in this knowledge base is Metacognition, and confusing the two is the most common error on the topic. Metacognition is the monitoring machinery: the in-the-moment judgments of whether you understand, remember or are on track. Reflection is a designed activity with a deliverable — a journal entry, a reflective essay, a portfolio commentary, a structured self-explanation prompt — performed after or alongside the work. The distinction acquires teeth in the AI era because the two are exposed differently: monitoring is hard to hand over and easy to displace, while a reflection artifact can be produced by a model, which makes the authenticity of the artifact rather than the depth of the thinking the first design problem.

Questions to Consider

- When you finish a difficult task, what is the difference between knowing you found it hard and actually working out *why* you found it hard? Which of those two does an end-of-week journal entry capture?
- A student submits a thoughtful three-hundred-word reflection that a model wrote for them. Is anything wrong with the document itself — and what exactly has the assessment lost?
- Several studies here find that adding reflection prompts *reduces* how much practice students complete while making them spend longer on each piece of Feedback. If reflection costs volume, when is that trade worth making?
- If a program can score a reflective essay for depth automatically, does that make reflection easier to teach or easier to fake?
- Teachers with less experience name lack of time as their main obstacle to reflecting; experienced teachers name tracking student performance. What does that imply for a single reflection tool rolled out to a whole school?
- Reflection is usually required, graded and prompted. What happens to a genuinely reflective habit when it becomes a compliance artifact?

Introduction

Reflection as an educational construct carries a family of models rather than a single definition: Kolb's cycle, Gibbs's structured stages, the DIEP framework, Schön's reflective practitioner, Mezirow's transformative reflection, and Boud's work on reflection in learning. The knowledge base's research treats these as a shared inheritance and then asks what generative AI changes about each of them. The recurring objects of study are reflective writing as an assessed genre, the journal or log as a routine, the e-portfolio as a container and an assessment form, and the prompt as the smallest unit of intervention.

Two further distinctions organize the literature. The first is *depth*: reflection is scored on levels, from descriptive retelling at the low end to critical, theory-informed examination of one's own assumptions at the

high end. The second is *author*. Until recently the second question did not arise. It now does, because the artifact and the thinking have come apart.

How reflection relates to self-assessment, metacognition and e-portfolios

The boundary work matters more here than on most concept pages, because four adjacent pages each own part of the territory, and practitioners routinely use the words interchangeably in rubrics.

What they **share** is real. All of them turn the learner's attention back onto their own work, all are associated with Learner Agency and self-awareness, all can be scaffolded and all can be performed for a grade. Every one of them is also being rewritten by generative AI in the same period, which is why the same studies recur across these pages. Reflection is the one in the group whose product is a *text*, and that is where the family resemblance stops being useful.

Where they differ is in what each leaves behind and what evidence counts.

Concept	Its core question	What it leaves behind	How reflection relates
Metacognition	Do I understand this, and how sure am I?	a judgment, often made in the moment	Monitoring can happen with no record at all; reflection is the deliberate examination that monitoring feeds
Self-Assessment	How good is my work against these criteria?	a rating, a score, sometimes a justification	One common *content* of a reflection; self-assessment needs no written reflection, and reflection can be about experience rather than performance
Self-Regulated Learning	What is my goal, what strategy am I using, and what do I change?	a planning-monitoring-adjusting cycle	Reflection is one phase inside the cycle, not the cycle itself
E-Portfolio	Where does the work live, and how is it curated?	an assembled set of artifacts with commentary	The container; curation becomes reflection only when someone asks the learner to explain the choices
Experiential Learning	What experience am I drawing on?	a cycle of action and abstraction	Supplies the material reflection works on
Feedback	What do I do with this information?	an uptake, a revision	The most common object of reflection

The practical consequence of keeping them apart is that each names a different thing to grade. A metacognitive judgment is correct or miscalibrated. A self-assessment is accurate or inflated. A reflection is specific or generic, evidenced or unsupported, and that is a property of the text rather than of the learner's state.

What reflection costs, and what it buys

The sharpest experimental test in this knowledge base is a preregistered between-subjects study with 302 US adults learning introductory Python. Asher, Gold and Carvalho (2026) compared a video crash course, practice with personalized AI feedback, and the same feedback paired with self-explanation prompts.

Reflection lost on nearly every measure. It roughly doubled time spent with feedback, 4.1 versus 2.1 minutes ($t(267) = 11.30$, $p < .001$), and cut practice volume by 40%, 2.0 versus 3.4 problems ($t(267) = 8.20$, $p < .001$). Each problem yielded the same learning gain with or without the prompts (Reflection × problem number OR = 1.03, $z = 0.23$, $p = .486$), so the practice arm finished with higher mastery, 79% versus 65% ($d = .41$).

The design lesson is not that reflection is useless. It is that a reflection prompt is a *competing* demand on scarce session time, and it can cost more than it returns when it arrives before the learner has finished an attempt.

When the reflection is not the student's

Authenticity is the live problem. Kadel et al. (2026) argue that the classical models have no strategy for a world where a reflection can be generated, and propose a GenAI-aware five-part structure: Purpose, Process, Product, Pitfalls, Plan. Its operational move is to require the documented trail — the prompts used, the iterations, the validation steps — rather than the polished final text, which is a "process over product" answer to the authorship question.

Others locate reflection inside the assessment machinery. Oktoma, Nugraha and Hidayat (2026) make structured reflection a live input that recalibrates the next feedback cycle instead of a post-hoc add-on. Pedlow and Maldon (2026) embed guided reflection inside pre- and post-semester Self-Assessment as a route to integrity and ethical confidence with GenAI.

The most useful caution comes from Dalsgaard and Prilop (2026), whose year-long study across eight Danish upper secondary schools (59 teachers, 48 students) found four GenAI practices — explanation, creation, inspiration, improvement — expanding into eleven processes, each of which can either support reflective thought or replace it.

An AI reflection partner can fail invisibly

A randomized trial had found that emerging adults reflecting on their careers with a GPT-4o conversational agent ended *less* committed to their plans than those using a static journaling survey. Nepal et al. (2026) coded all 17,930 turns to find the cause.

Every rule the agent followed was one that could be checked mechanically: a reply-length cap, for instance. Rules about how to behave — do not flatter, challenge gently — were broken without leaving a visible trace in the transcript. The behavior tied to added doubt was a repeated demand to decide when participants hesitated.

That finding generalizes beyond career reflection. An AI reflection partner degrades in the one place its output looks fine, so the artifact cannot serve as evidence that the conversation was good.

Scoring reflective writing at scale

Depth is measured, and increasingly automated. The Hungarian reflection-level study (2026) used 1,954 expert-annotated essays written over four consecutive years in an Early Childhood Education program, comparing classical models on TF-IDF features and Qwen3 embeddings against two fine-tuned Hungarian transformers.

The corpus is severely skewed: 68% of essays sit at level 3 and only 1.8% at level 0, so much of the paper is imbalance handling. Shallow models reached up to 71% on an averaged accuracy-F1-ROC AUC score; the transformers reached 68% overall but handled minority levels better.

The measurement lesson is narrower than it looks. A classifier estimates how reflective a text reads. It cannot tell whether the reflection happened, and it is exactly the level of performance a fluent model can imitate.

Journals, portfolios and prompts as delivery systems

The construct is usually delivered by three vehicles, and each has its own failure mode.

Routine journaling fails to motivation decay. Scheu et al. (2026) ran a randomized 2×2 field experiment with 179 German university students over 22 days with a 12-week follow-up, testing an example-based seven-day course and an Large Language Models (LLMs) journaling assistant that summarizes drafts, asks clarifying questions and offers alternative formulations. Sustaining the routine, not designing the prompt, was the hard problem.

Portfolios fail when the container substitutes for the act. Ni and Lam (2026) followed 50 first-year Tourism Management students through 16 weeks of WordPress e-portfolios with GenAI as a feedback provider and a synthesizer of peer and teacher comment, tracing multiliteracies development across three stages. Sutama (2026) tested ChatGPT aligned with e-portfolio assessment against a control in 60 vocational EFL students and found a large simultaneous effect (Wilks' $\lambda = 0.476$, $p < .001$, partial $\eta^2 = 0.524$), with speaking at 82.733 versus 78.833 and Feedback Literacy at 79.666 versus 71.762.

Prompts fail when they are inserted at the wrong moment, as the Asher study shows.

Reflection in professional learning

For teachers the construct doubles as professional development. Falhs (2025) surveyed 100 US K–12 teachers and found needs that diverge by experience: less experienced teachers cite lack of time as a top obstacle far more often, 37% versus 12% ($p < .001$), while experienced teachers more often report difficulty tracking student performance, 28% versus 15% ($p = .009$). Informal feedback motivates experienced teachers more, 45% versus 31% ($p = .025$). A single reflection tool for a whole school is therefore mis-specified by design.

Ho and Chen (2026) add the process view from 18 teachers in mainland China and Hong Kong, whose accounts resolve into recognizing the need to use GenAI, redistributing cognition, and reflectively re-engaging after use. The Reflective Triangle Model (2026) connects self-reflection, collaborative reflection and community reflection across a professional learning community in a four-week case with six teachers, with AI as a cognitive mediator rather than an evaluator.

Preparation also matters independently of the tool. Zhang et al. (2026) crossed metacognitive strategy training against a placebo module with an LLM configured as a Socratic reflection partner versus traditional digital tools, in a 2 × 2 design with 60 pre-service teachers. Both main effects were significant for written reflection quality at post-test.

The risk that a reflection prompt replaces the monitoring it means to build

de Jong (2026) raises the field's untested assumption: cognitive forcing, pre-commitment and uncertainty communication reduce overreliance within a session, but nothing establishes that they build durable self-monitoring rather than habituating the user to prompts. A mechanism that supplies reflection can substitute for the monitoring it was meant to develop.

Two designs respond to that worry differently, and both are useful signals. PAUSE (Alam, 2026) is a privacy-by-design self-check that turns the empirical literature on Cognitive Offloading into descriptive, non-diagnostic reflections across four domains, with no composite score and an explicit refusal to justify any consequential decision. Wang and Zhao (2026) treat reflective AI use as a measurable construct, finding acceptance predicting it at $\beta = 0.774$, and reflective use predicting Self-Efficacy at $\beta = 0.519$ and engagement at $\beta = 0.273$.

Guidance for practitioners

Designing the reflection task

- **Sequence the prompt after an attempt closes.** The 302-adult experiment is the cautionary case here: prompts that interrupted work between an attempt and its feedback spent the session's time and shrank how much practice was completed.
- **Name the depth level you are rewarding.** The Hungarian corpus scores reflection on levels from descriptive retelling to critical examination of assumptions. A prompt asking students to "reflect" while the rubric rewards description produces descriptions.
- **Prompt for the episode, not the term.** "What did you try, what failed, and what did you change on the third attempt?" is answerable. "Reflect on your learning journey" is not.
- **Ask for the process trail.** Recorded prompts, abandoned drafts, a rejected approach and the reason for the final choice are all cheap to produce, hard to fake, and exactly what the GenAI-aware models put first.

A starter prompt that survives most of the failure modes above: *(1) What did you try, and what did the result tell you? (2) Which AI output did you accept, and what did you check before accepting it? (3) What will you do differently on the next attempt, and why?* Each question asks for something a student has to know rather than something a model can supply, and question two is what turns an AI-use policy into a reflection task.

Making AI use explicit rather than forbidden

- **Reward disclosure.** A reflection that documents how GenAI was used, checked and corrected is more useful evidence than one that omits it, and the five-part GenAI-aware model is built on that premise — Purpose, Process, Product, Pitfalls, Plan.

- **Set the policy inside the prompt.** State what may be delegated and what must be the student's own observation; a policy in a syllabus is invisible at the moment of writing.
- **Keep the AI in the questioning role.** A partner that asks clarifying questions and offers alternative formulations preserves the learner's articulating work; one that writes the entry removes it.
- **Audit any reflection agent you deploy.** In the one coded audit in this knowledge base, the agent obeyed mechanically checkable rules and broke the behavioral ones without leaving a trace, while looking perfectly plausible.
- **Do not turn a wellbeing-oriented self-check into a diagnosis.** The PAUSE design is the model here: descriptive, domain-aware reflections, no composite score, and an explicit refusal to justify any decision about a person.

Grading authenticity

- **Grade what you can defend.** Specificity, evidence of a decision, revision reasoning and honesty about what went wrong are gradeable. Sincerity is not, and a fluent model can imitate the surface of all of it.
- **Pair the artifact with something expensive to delegate.** A short verbal defense, a live revision, or a decision that has consequences — the Prober system's reflective gate and Issa and Hall's per-member verification meetings are two working patterns.
- **Watch what grading does to the act.** When self-reflection is graded it risks becoming performative, so state what the reflection is *not* assessed for and keep at least some reflection ungraded.
- **Never treat a score as proof of thinking.** Depth classifiers estimate how reflective a text reads, which is a property a fluent second draft can manufacture.

Sustaining the routine

- **Design for motivation decay, not for prompt quality.** Reflective journals are abandoned within weeks; example-based onboarding and a conversational assistant that asks questions were the two interventions this corpus tests against that.
- **Favour frequency over length.** A short entry after each attempt sustains the habit; a long entry at the end of term is a single writing task with a reflective label.
- **Give the portfolio a reflective checkpoint.** Without a commentary requirement at each curation point, an e-portfolio becomes a museum of finished products.
- **Adapt to expertise.** Less experienced teachers cite time as their top obstacle; experienced teachers cite tracking student performance, so one reflection interface across a whole staff serves neither group.
- **Pair tool access with preparation.** Metacognitive strategy training and a Socratic AI partner each improved written reflection quality on their own in the pre-service experiment, which suggests the preparation is not optional Scaffolding for the tool.

Common Misconceptions

- **“Reflection and metacognition are the same thing.”** They are related but separable. A judgment about your own state of understanding and an activity that leaves a record behind are different objects of study, which is why this knowledge base keeps them on separate pages.
- **“Reflection is always worth the time it takes.”** At least one preregistered experiment found the trade unfavourable, because the reflection competed with practice for the same session minutes.
- **“A deep-sounding reflection means deep thinking happened.”** Reading as reflective and being reflective are different properties, and a fluent model can supply the first.
- **“Automated scoring solves the scale problem.”** Classifiers reach roughly 70% on reflection level in a well-annotated corpus with severe class imbalance, and that ceiling is within reach of plausible text.
- **“Portfolios are reflective by nature.”** The container is not the act; a portfolio assembled from polished products can contain no reflection at all.
- **“Reflection needs no teaching.”** Both the Hungarian essay corpus and the pre-service teacher experiment presuppose that level and quality are learned, and that preparation changes outcomes.

Desirable Difficulties

> **Desirable difficulties** — the finding (Bjork) that harder, effortful retrieval conditions — spacing, retrieval practice, interleaving, and generation — improve long-term learning more than easier, massed conditions — is the theoretical counterweight to AI that smooths away cognitive work. In the AI era the principle warns that tools which eliminate productive struggle may raise immediate performance while undercutting durable learning. **Desirable difficulties, cognitive friction, and productive friction are used as overlapping synonyms** for this intentional effort: the knowledge base treats them as the same core idea viewed from different fields, with the nuances between the labels spelled out in the section below. Closely allied concepts — **confusion**, and **productive struggle** — mark the zone where this effortful processing is expected (and desirable) to occur.

Questions to Consider

- Have you ever felt you understood something because it felt easy and fluent in the moment — only to fail when you had to recall it later? That's the illusion of competence. What created it for you?
- Desirable difficulties say that effortful conditions — spacing, retrieval practice, interleaving — build durable learning better than easy, massed ones. Where in your own learning have you resisted a 'harder' strategy that probably would have worked better?
- Generative AI is, by default, a friction-removing machine: it answers instantly and produces polished output on demand. If removing struggle raises immediate performance but undercuts durable learning, how would you know whether an AI is helping or harming a student?
- This page distinguishes desirable difficulties (memory optimization from cognitive psychology) from productive/cognitive friction (engagement Guardrails from UX design). Can you see why the same educational goal needs both — and where they'd diverge?
- Some AI tutors are found to 'over-scaffold' — removing the very effortful processing desirable difficulties require. If you were evaluating an AI tutor, what concrete behavior would tell you it's preserving productive struggle rather than collapsing to answer-giving?
- Confusion is framed here as a resource, not a bug — when resolved productively it drives deep processing, but unaddressed it decays into frustration. Where's the line between productive struggle worth preserving and frustration that's just harmful?

Introduction

Desirable difficulties are the conditions of practice that make learning feel harder in the moment — effortful retrieval, generation and explanation, spacing, interleaving — yet produce stronger retention and Transfer of Learning than conditions that feel easy. The same phenomenon appears in the literature as **cognitive friction** and **productive friction**, labels borrowed from human–computer interaction and UX design that emphasize deliberately placing resistance between a learner and an easy answer; the families overlap but are not identical, and the differences are set out below. Because generative AI is optimized to be frictionless, the

concept has become a first-order design concern rather than a niche finding: systems that answer instantly remove difficulty that may have been doing the learning (Cognitive Offloading, Scaffolding).

The Effort–Learning Trade-Off

Desirable difficulties rest on the insight that conditions that make learning feel harder in the moment — requiring effortful retrieval, generation, or explanation — frequently produce stronger retention and transfer than conditions that feel easy. Conversely, conditions that feel easy (fluent presentation, immediate answers) can produce an illusion of competence: Learners feel they know the material because recognition was smooth, while later free recall fails. This is the theoretical core of the **performance–learning gap**: what looks like good performance during practice is not the same as durable learning.

Effort that buys nothing is not a desirable difficulty. In a preregistered experiment with 302 adults learning introductory Python, adding self-explanation prompts to already-elaborated AI feedback doubled time on feedback (4.1 vs 2.1 minutes) and cut problems completed from 3.4 to 2.0, with final-problem scores of 45% against 60% (d = .41) (Asher, Gold & Carvalho, 2025). The boundary the study locates: difficulty is desirable when it drives additional retrieval, application or comparison, and redundant when the learner already has a personalized explanation of the specific error.

Confusion, Cognitive Friction, and Productive Struggle

Three related constructs describe the zone in which desirable difficulties operate:

- **Confusion** — a learning *epistemic emotion* (see Affective Computing and Ordered Network Analysis of Epistemic Emotions during Collaborative Problem Solving) that signals a gap between a learner's mental model and incoming information. Confusion is not uniformly bad: when resolved through productive inquiry it can drive deep processing, but when unaddressed it can decay into frustration or disengagement. AI systems increasingly detect confusion (e.g. capture buttons, affective sensing) to anchor personalized support — as in From Confusion to Consolidation: A Staged Conversational Workflow for Post-Lecture Review, where marked confusion points become review anchors and teach-back prompts surface conceptual gaps.
- **Cognitive friction** — the deliberate resistance a learning environment places between a learner and an easy answer, forcing them to think before receiving help. AI tools that answer instantly remove this friction; designs that withhold, hint, or scaffold preserve it. Stop Writing for Me: Generative Refusal in AI Tools for Thought, Assessing the Impact and Underlying Pathways of Sequenced AI Feedback on Student Learning, and Scaffolding critical thinking with generative AI: Design principles for integrating large language models in higher education each examine how intentionally preserved friction supports reasoning.
- **Productive struggle** — the effortful phase of problem solving in which a learner wrestles with a challenge before (or while) receiving support. The knowledge base's evidence base documents both its value and its cost: Faster Completion, Less Learning: Generative AI Reduced Study Time on Math Problems and the Knowledge They Build shows removing struggle reduced study time but impaired learning, while Curiosity as Linguistic Intervention: Using LLM Tutoring Dialogues to Influence Exploratory Learning Behavior and Rethinking Scaffolding in LLM Tutors: The

Interactional Mismatch Between Benchmarks and Real-World Deployments explore how tutors can keep learners in the productive-struggle zone rather than collapsing to answer-giving.

Productive failure is the structured, theory-driven version of this idea: Kapur's productive failure (PF) formalizes productive struggle as a two-phase design (generation & exploration *before* instruction, then consolidation & knowledge assembly). The AI-era PF literature gives the knowledge base a concrete design vocabulary for preserving desirable difficulty — Kim et al. (2026) derive AI design principles (human-AI collaboration, reflective design, non-directive support) that keep AI from erasing the struggle; Puech et al. (2025) show Large Language Models (LLMs) tutors can be steered to withhold solutions and elicit multiple attempts; Wang & Shan (2026) formalize the "Safety Gap" — the divergence between AI-assisted performance and unassisted capability — as the cost of removing struggle; and ProductiveMath uses AI to lower the burden of designing PF problems. These show that desirable-difficulty principles translate into concrete AI design choices.

Constraint can carry the same design logic inside a writing classroom. In a nine-week argumentative-writing unit, Konradt, Boote and Taub (2026) gave four high-school students teacher-delimited chatbots that asked questions instead of generating prose; students pushed back on AI output instead of consuming it, developing prompt literacy alongside counterargument and evidence-integration gains.

Desirable Difficulties vs. Cognitive Friction vs. Productive Friction

Because AI is designed to be frictionless — instantly generating summaries, solving equations, and writing essays — it can inadvertently bypass the very struggle required for a student to learn. To combat this, educators and technologists rely on two overlapping but distinct frameworks: **desirable difficulties** and **productive (or cognitive) friction**. Both advocate making things harder for the learner, but they originate from different fields and target different parts of the learning process. In this knowledge base they are treated as synonyms for the same intentional-effort idea; the table below details the nuance between the labels.

Feature	Desirable Difficulties	Productive / Cognitive Friction
Primary goal	Maximizing long-term memory and knowledge transfer	Preventing Cognitive Offloading and maintaining active engagement
Scientific root	Cognitive science & psychology (Bjork, 1994)	Human–Computer Interaction (HCI) & UX design
The "threat"	The illusion of competence (thinking you know it because it feels easy now)	Automation bias (letting the machine do the thinking for you)
AI implementation	Algorithms that time and structure practice (spacing, interleaving, retrieval)	Chatbot guardrails and UI roadblocks that force the learner to do the work

Desirable difficulties: the memory optimizer. Coined by Robert and Elizabeth Bjork (1994), this framework comes from cognitive psychology. Its core idea is that learning strategies which feel harder and slow initial performance actually produce better long-term retention and transfer. Desirable difficulties are about *how the brain encodes and retrieves information*: if learning feels too easy or fluent in the moment (like re-reading a highlighted textbook), the brain likely isn't doing the deep processing required to make the memory stick. In AI, a tool using this framework changes the *Pedagogies and Teaching Strategies* of the

session — for example, asking the student to retrieve from memory before offering a summary (retrieval practice), scheduling review just before forgetting (spacing), or mixing problem types (interleaving) rather than grouping them by category. Notably, the benefit of these effortful strategies is itself content-dependent: Rachatasumrit, Koedinger & Carvalho (2025) show that retrieval practice chiefly strengthens verbatim memory (by delaying forgetting), whereas acquiring a generalizable skill requires integrating worked examples with practice — so the "difficulty" that helps must be matched to the type of knowledge being learned rather than applied uniformly.

Productive (cognitive) friction: the engagement guardrail. This framework comes from UX and interaction design, where "friction" is normally the enemy (one-click checkout, instant search). In educational technology, zero friction means zero thinking: productive friction introduces intentional "speed bumps" into the software to prevent the user from offloading cognition to the machine. It is about the *interaction between human and machine*, keeping the user actively engaged and preventing automation bias — blindly trusting the AI's output without evaluating it. In AI, a tool using this framework changes its *behavior and design* to prevent shortcuts — for example, a Socratic guardrail that withholds the direct answer and asks what symbols the student noticed, effort checkpoints that refuse to generate a draft until a thesis and outline are entered, or delayed Feedback that requires committing to an answer and explaining reasoning before the solution is revealed.

In short: you use productive friction to ensure the student actually interacts with the material instead of letting the AI do the heavy lifting; you use desirable difficulties to structure *how* they interact with that material so they remember it a month from now.

Desirable Difficulties in the AI Era

The central tension for AI-supported learning is that generative AI is, by default, a friction-removing technology: it answers, generates, and produces polished artifacts on demand. Across the knowledge base, this plays out in two directions:

- **The cost of removing struggle.** When AI erases spacing, retrieval, and generation, learners may show immediate performance gains but forfeit durable learning and transfer. This connects directly to the Over-Reliance and AI Misuse and Learning Harm findings: an AI that removes desirable difficulty produces the performance–learning gap documented across the knowledge base's evidence base. Agentic AI and Pedagogical Best Practice: The Tension Between Automation and Learning calls explicitly for intentional friction. Barcaui's (2025) randomized trial gives the principle a direct delayed test in an AI setting: 120 undergraduates who studied AI/ML topics with unrestricted ChatGPT scored 57.5% on a surprise retention test 45 days later against 68.5% for traditional learners ($t(83) = -3.19$, $p = .002$, Cohen's $d = 0.68$). The deficit held with study time as a covariate ($F(1, 82) = 7.89$, $p = .006$). The impairment was largest on technical topics ($d = 0.92$) — the material where AI offered the most assistance, and where the struggle the principle says is productive is most needed.
- **The cost also arrives late.** A difference-in-differences panel of 26,811 Chinese secondary students found homework scores up 18% and completion time down 30% while closed-book exam scores fell 20% within six months. Entrance-exam scores fell 18% (Gaokao) and 24%

(Zhongkao), with the full penalty emerging only after about two years (Strömberg, Lei & Wu, 2026). A delay measured in weeks can show the direction of the trade-off but not its size.

- **Same model, two guardrails, opposite outcomes:** students given unrestricted GPT-4 used it as a crutch and performed worse than controls once it was removed, while students given a guardrailed tutor performed like controls — friction, not the model, decided whether the tool helped (Arthars et al. (2026)).
- **Designing struggle back in.** Instructional designs can deliberately preserve productive processing: draft-first routines, hint-not-answer tutoring, delayed feedback, and teach-back/explanation protocols. These are the concrete scaffolds explored under Reducing AI Misuse and The Effects of Structured LLM-Generated Feedback on Programming Assignment Performance. A 2026 conceptual extension (Gupta) pushes the same logic beyond structured academic tasks to difficulty inside relational encounters: in education abroad it argues the educational question is not how much generative AI is present but which difficulties it dissolves, and proposes a *mediation gradient* that orders uses by the interpretive Learner Agency transferred to the system rather than by volume of use.

The inverted U and the effort paradox. Zohar, Bloom and Inzlicht (2026) supply the sharpest recent statement of why AI's friction-removal is not automatically good. They distinguish AI from earlier labor-saving technologies on two grounds. It targets intellectual and creative work rather than physical or clerical work, and its friction removal is *extreme*. Prior technologies eliminated excess friction, "tedious or insurmountable obstacles that offer little benefit for learning or meaning". A chatbot, by contrast, lets a learner move from ideation to evaluation "without exerting meaningful effort, without questioning the output, and without engaging the cognitive processes that foster ownership, retention, or critical thought". Their organizing claim is that the effort–meaning relationship is curvilinear: moderate friction enhances meaning and motivation while excessive friction overwhelms, so AI's risk is overshooting into too little friction rather than excess. Two consequences matter pedagogically — effort is itself a trainable skill (rewarding process rather than product increases the tendency to strive and persevere), and the motivational benefits of effort erode in exactly the domains where AI substitutes for it, producing a cycle of increasing dependence (Cognitive Offloading, Motivation).

Design Implications

1. **Do not optimize for effort-free fluency.** An AI tutor that always answers immediately may raise satisfaction while lowering durable learning; favor interventions that require retrieval and generation first.
2. **Treat confusion as a resource, not a bug.** Detect and target confusion points as personalized review anchors rather than smoothing them away — the KnowLoop Recognize → Resolve → Consolidate model is a concrete pattern.
3. **Preserve cognitive friction deliberately.** Use hint-not-answer Scaffolding, sequential feedback, and refusal-to-answer where the goal is reasoning, not production.
4. **Match friction to learner readiness.** Desirable difficulties benefit learners who can engage in effortful processing; over-challenge without support risks frustration. Scaffolding must keep learners in the productive-struggle zone, not past it.

TutorMoments operationalizes desirable-difficulty principles as evaluation criteria: Zhang et al. (2026) test whether AI tutors preserve productive struggle by scaffolding for access (when needed) and pushing for rigor (when ready), and find that LM tutors default to over-scaffolding — removing the effortful processing that desirable difficulties require.

Common Misconceptions

"Ease and fluency during study indicate that learning is happening." They often indicate the reverse. Fluency is a cue that correlates weakly or negatively with durable retention, and the AI-era version has a direct delayed test: Barcaui's (2025) randomized trial found that **120 undergraduates** who studied AI/ML topics with unrestricted ChatGPT scored worse on delayed retention — with the impairment **largest on technical topics (d = 0.92)**, the material where AI offered the most assistance. The condition that felt most helpful produced the largest deficit.

"Struggle is therefore good and discomfort should be preserved." Not all friction is desirable. The construct is specific: difficulties are desirable when they require retrieval, spacing, interleaving or generation, and undesirable when they are incidental confusion, poor interface, or an absent prerequisite. Preserving confusion that teaches nothing is as much an error as removing the effort that teaches.

"Cognitive friction and productive struggle are the same idea." They come from different literature and make different predictions. Productive struggle concerns effortful sense-making that builds understanding; cognitive friction concerns the mismatch between what a task demands and what the learner's current resources support. Treating them as synonyms loses the diagnostic question — is this learner struggling in a way that builds, or blocked in a way that only costs?

"If removing struggle raises immediate performance, the intervention worked." This is the trade-off the whole page is about: performance measured in the presence of the support is systematically inflated relative to later unassisted performance. Any evaluation of an AI that reduces effort must measure at delay and without the tool, or it will report the removal of practice as the production of learning.

- How Should I Use AI to Study and Learn Effectively?

Transfer of Learning

> **Transfer of Learning** — the extent to which knowledge or skills acquired in one context (e.g., practice with an AI tool) persist and apply in a different context (e.g., independent performance without the tool). In AI in education, transfer is the central open question: whether performance gains students show *with* AI tools translate into durable learning they can demonstrate *without* them.

Questions to Consider

- Here's a striking pattern the page documents: students often show immediate gains on AI-assisted tasks, yet those gains can vanish — or even reverse — when the AI is removed. Before reading the explanations, why do you think a tool that clearly helps in the moment could end up leaving students worse off without it?
- Recall something you learned to do with a tutor, calculator, or assistant and then had to do alone. Did the skill carry over, or did you feel dependent on the aid? What was different about the experiences that transferred well versus those that didn't?
- A common intuition is that 'practice is practice' — that doing a task with help builds the same skill as doing it alone. Where might that intuition mislead, especially when the help is an AI that completes the reasoning for you rather than guiding you through it?
- The page draws a distinction between 'effects with' a technology and 'effects of' it — performing better while using the tool versus becoming more capable without it. If you're an instructor, designer, or student, which of these is your real goal, and how would you know you'd achieved it?
- The evidence suggests that how much cognitive work you delegate matters: offloading surface tasks like grammar hurt transfer less than offloading deep reasoning and structure. Think about the last time you used AI on an assignment. Which 'layer' did you delegate, and what does your choice predict about what you'd retain?
- The page proposes conditions that might support positive transfer — pedagogical Guardrails, fading support, calibration to the learner's readiness. If you were designing (or were the user of) an AI learning tool, what would you insist on so that gains while using it become durable ability without it?

Introduction

Transfer of learning is a foundational concern in education research, and AI tools have made it urgent. The defining empirical pattern documented across AI in education studies is a **transfer paradox**: students using AI typically show immediate, measurable gains on tasks where AI is available, but those gains often fail to persist — or even reverse — when AI is removed and students must demonstrate understanding independently. This pattern implicates Over-Reliance, Cognitive Load Theory, and Metacognition as the mechanisms at work, and connects directly to debates about AI Tutoring design.

Readiness is not transfer: AI-assisted spoken practice was associated with lower speaking anxiety and higher willingness to communicate with humans, yet neither study observed human speaking, leaving the route from AI rehearsal to human communicative ability an untested pedagogical proposal (Wang & Li (2026)).

The transfer paradox

Students using AI typically show **immediate, measurable gains** on the tasks where AI is available. Yet when AI is removed:

- Effects become **mixed or negative**
- Gains often **fail to transfer** to unassessed settings
- Students may become **dependent on the tool** at the expense of independent reasoning

The evidence base, synthesized in the Stanford Evidence Base on AI in K-12 review, is consistent across domains:

Study	Context	Immediate Effect	Transfer Effect	Mechanism
Bastani et al. (2025)	High school math	Higher practice grades	**~17% worse** on closed-book finals	General-purpose chatbot did the work
Chen et al. (2025)	Programming homework	Higher homework scores	**No improvement** on unassisted exams	Large Language Models (LLMs)-Tutor solved problems for students
Lehmann et al. (2025)	Programming	More topics covered	**Harmed understanding**; widened gaps	General AI for low-prior learners
Stadler et al. (2024)	Academic research	Faster task completion	**Lower-quality reasoning** vs. search	Reduced cognitive engagement
Kosmyna et al. (2025)	Essay writing	Higher essay quality	**83% failed to recall** their own quotes	Outsourced authorship

All five studies show a **negative or null transfer** pattern when general-purpose AI is the intervention.

Mechanisms undermining transfer

Metacognitive displacement. AI completing reasoning reduces opportunities for students to monitor their own understanding and select strategies. Students who used AI were less able to explain their answers when queried. This connects to Metacognition research on self-monitoring and the evidence that structured courses increase metacognitive competence while raw LLM assistants do not.

Germane load suppression. General-purpose AI reduces not just extraneous (distracting) cognitive load but also *germane* load — the productive mental effort that encodes durable knowledge. Easier practice feels better but stores weaker traces. See Cognitive Load Theory and the distinction between tutoring-specific vs general AI.

Over-reliance / expertise reversal. Novices given answers do not build schemas. General AI provides answers; effective tutoring provides structured guidance. When novices are given expert-level shortcuts, learning is disrupted — the Desirable Difficulties principle in reverse.

Tool-dependent performance. Students may optimize for the specific affordances of the AI tool (prompt engineering, reliance on generated code structure) rather than building domain generalization — a form of cognitive offloading that feels productive but displaces durable learning.

A protected classroom can also teach the wrong habit: Shi, Dai & Zhang (2026) warn that simulations with rules fixed in advance filter out uncertainty and reinforce rule-following, so decision habits formed inside them can become a cognitive liability once students meet competing interests and incomplete information in real settings. **Layer-sensitive offloading and transfer.** Chen (2026) directly tests Salomon, Perkins & Globerson's "effects with vs. effects of technology" distinction in GenAI-assisted writing: an eight-week quasi-experiment found open AI collaboration maximized supported-writing performance but produced the *lowest* independent no-AI near-transfer outcomes, while bounded support with reflection preserved independent competence. Deeper offloading layers (reasoning, structure) predicted worse transfer than surface layers (grammar). This is direct classroom evidence that AI's *with*-support performance gains do not transfer to *of*-support independent performance — and that the depth of delegation, not just whether AI is used, shapes transfer.

A complementary, if confounded, instance comes from physics: the Ruhr University Bochum redesign of an introductory nuclear and particle physics course (Mikhasenko et al., 2026) had students successfully complete collaborative, resource-rich research problems with AI assistance, yet those same students averaged 20.6/80 on a conventional unaided written exam, with several serious attempts unable to complete standard calculations. The authors read this as evidence that assisted performance does not automatically transfer to unprompted performance, and their remedy is deliberate design: making the written exam the sole grade determinant, releasing tutorial problems in advance so class time becomes prepared discussion, and adding prerequisite preparation, worked examples and consolidation around the exploratory AI-permitted work.

Conditions supporting positive transfer

The limited evidence suggests transfer is possible when:

- **Pedagogical guardrails are present** — step-by-step hints, misconception targeting, Socratic questioning (Bastani et al., 2025 tutoring variant)
- **Traditional strategies are preserved** — note-taking paired with AI use improved retention (Kreijkes et al., 2026)
- **AI is used for formative, not summative, practice** — scaffolding during learning, not during assessment
- **The practice format is matched to the knowledge being transferred.** Rachatasumrit, Koedinger & Carvalho (2025) find that retrieval-practice gains frequently fail to transfer to unfamiliar problems — they strengthen memory for a procedure without enabling its use in new contexts — and that durable generalization to novel applications requires pairing practice with

worked examples that support skill induction; the optimal example–problem ratio therefore depends on whether the content is a verbatim fact or a generalizable skill.

- **Learner expertise is calibrated** — the tool adapts support to readiness rather than defaulting to full assistance
- **Transfer as the criterion that separates learning from assistance.** Yan and Gašević (2026) build their theory of human-AI learning around transfer under reduced support: assisted performance counts as learning only if the capability persists once the support is withdrawn, which makes transfer the test rather than one outcome among several. Their proposition is directional, that requiring source checking or justification during AI-supported work should improve delayed performance, while repeated low-friction delegation without reconstruction should weaken learners' calibration of their own competence.
- **Guidance is co-located with the work.** Against the negative-transfer pattern in the table above, a 36-participant comparison found learners assisted by a desk robot held their score at 7.0/10 once help was withdrawn while ChatGPT-assisted learners fell to 4.4/10, a 60% higher short-term transfer score (Orlando et al. (2026)). The result is short-term transfer measured about 35 minutes after the task, with no delayed retention test, in 36 participants at one campus.

This aligns with AI Tutoring research showing that tutoring-specific tools with pedagogical guardrails outperform general-purpose chatbots, and with Scaffolding principles about fading support as competence grows.

Unanswered questions

1. **Time scale:** Does transfer improve over weeks/months of use, or does dependence deepen?
2. **Domain differences:** Is transfer better in well-structured domains (math) vs. ill-structured domains (writing)?
3. **Individual differences:** Do high-Prior Knowledge students suffer less transfer loss than novices?
4. **Skill remediation:** Can explicit "AI-off" practice sessions reverse tool dependence?

The time-scale question now has a formalization. Yajee (2026) names the post-withdrawal interval cognitive washout and gives it four candidate outcomes: elastic rebound, partial plateau, latent scaffold and over-recovery. Reversibility, the paper argues, is what determines severity, and it proposes a preregistrable three-arm, twenty-two-week protocol to measure it. The studies above tested transfer hours after assistance ended, so the weeks afterward are the part of this page's first open question that remains genuinely unmeasured.

Connections to related concepts

Transfer of learning connects to Metacognition (self-monitoring of understanding), Cognitive Load Theory (germane vs extraneous load), Desirable Difficulties (productive struggle), Scaffolding (fading support), Over-Reliance (tool dependence), and Sociocultural Learning (general-purpose AI operates outside the ZPD by completing work for students). It is the bridge between assisted performance and genuine learning — the distinction between The Evidence Base on AI in K-12: A 2026 Review and the central question for AI Tutoring effectiveness.

Common Misconceptions

“Gains on AI-assisted tasks demonstrate transferable learning.” The opposite pattern is what the corpus finds: **all five studies** in the synthesis reported here show **negative or null transfer** when general-purpose AI is the intervention — high school mathematics students with higher practice grades scoring **about 17% worse** on closed-book finals, and an essay-writing study in which **83% failed to recall their own quotes**. Immediate assisted performance is the least transferable measure available.

“If a student can do it with the AI, they can do it.” That is the definition of the failure rather than its absence. Transfer requires that the capability survives removal of the support, and the studies that test removal find the capability was in the tool. A learner who can produce an artifact while the reasoning is performed elsewhere has been trained in a different skill: operating the tool.

“Transfer comes from more capable models.” Transfer comes from conditions that produce it — the generality of the practice, the variability of the contexts, and the extent to which the learner generated the reasoning themselves. Model capability raises the ceiling on assisted performance and does nothing in particular for what remains when the model is gone.

“Guidance always supports transfer, so more guidance is better.” Guidance that performs the reasoning substitutes for the process transfer depends on. The distinction is between help that keeps the learner generating the next step and help that generates it for them — and only the first is on the transfer side of that line.

Prior Knowledge

> **Prior knowledge** — the existing knowledge, skills, beliefs, and mental models a learner brings to a new learning task. It is the single most powerful predictor of subsequent learning: new information is interpreted through — and integrated with — what the learner already knows, so instruction that activates and builds on prior knowledge produces stronger, more durable learning than instruction that treats every learner as a blank slate. In AI in education, prior knowledge is central to Learner Modeling and Adaptive Instruction (adapting instruction to the learner's current state), to the Constructivism principle that knowledge is actively constructed atop existing mental models, and to the risk that AI tools which pre-fetch and surface content bypass the retrieval practice that activates prior knowledge.

Questions to Consider

- What's something you learned deeply and something you struggled to learn? How much of the difference came down to what you already knew when you started?
- Having prior knowledge isn't enough—it must be actively retrieved and connected. When has recalling what you already knew (or failing to) changed how well you learned something new?
- The page says prior knowledge can *interfere* when it's wrong (a misconception). Can you think of a belief you held that made new, correct information harder to learn?
- Generative AI that pre-fetches answers can bypass the retrieval practice that activates prior knowledge. How might a tool designed to help you learn actually prevent you from recalling what you know?
- If an AI must estimate your prior-knowledge state to personalize, what happens when that estimate is wrong? How confident are you that a system could accurately know what you already know?
- How is 'activating prior knowledge' different from simply asking students a question before teaching? What would make that activation genuinely deepen the learning that follows?

Introduction

Prior knowledge activation is one of the most robust findings in the learning sciences: learners do not absorb new material in a vacuum but map it onto existing schemas, and the quality of that mapping determines retention and transfer. The concept underpins Ausubel's advance organizers, activation of prior knowledge before new instruction, retrieval practice as a form of activating and strengthening what is known, and diagnostic Assessment of what learners already know. In the AI era, prior knowledge has taken on new urgency because generative AI can either *support* activation (prompting learners to recall and connect what they know) or *bypass* it entirely (instantly supplying an answer or pre-fetched content that the learner never had to retrieve or integrate).

The role of prior knowledge

- **It is the strongest predictor of learning.** Decades of research show that what a learner already knows correlates with learning outcomes more strongly than almost any other factor, because new information is encoded relative to existing mental models. AI systems that adapt to each learner's prior-knowledge state therefore hold particular promise for efficiency and transfer.
- **How much stronger, in one randomized comparison.** Two otherwise identical second-grade mathematics tutors, differing only in whether task selection followed a Bayesian knowledge-tracing mastery estimate, produced no difference in posttest scores. Prior knowledge predicted those scores at $\eta^2p = .63$ ($F(1, 124) = 206.99$, $p < .001$) while the adaptive sequence accounted for $\eta^2p = .00$ (Sibley, Berner and Schmalfeldt (2026)). Adaptation rearranges the order of practice; what the learner brought to it still carried the outcome.
- **Activation matters, not just possession.** Having prior knowledge is not enough — it must be actively retrieved and connected to the new material. This is why "activating prior knowledge" is a standard instructional move, and why retrieval practice (recalling what you know before adding to it) improves learning beyond simple re-exposure.
- **It does not always predict who does the work that drives learning.** In a five-day Learning by Teaching study with 23 middle-school tutors, prior test scores did not predict the share of knowledge-building responses a tutor produced, and low-prior tutors who built knowledge finished statistically level with high-prior peers (Ameen et al., 2026).
- **It shapes interpretation.** Learners interpret new information through what they already believe. When those beliefs are wrong (Misconceptions about AI), prior knowledge can *interfere* with learning, which is why instruction must surface and address misconceptions rather than assume a neutral starting point.
- **It drives student modeling.** To personalize, an AI system must estimate the learner's prior-knowledge state — the basis of Knowledge Tracing, student modeling, and adaptive Scaffolding. The quality of these estimates determines whether adaptation is genuinely helpful or misleading.
- **Knowledge content determines which process practice recruits.** Whether learning hinges on memory or on induction is set by the prior-knowledge structure of the target: Rachatasumrit, Koedinger & Carvalho (2025) follow the KLI framework in distinguishing knowledge components with constant conditions and responses (facts, acquired through memory and retrieval practice) from those with variable conditions and responses (skills, acquired through induction and generalization to novel inputs) — which is why the optimal mix of worked examples and practice differs for fact content versus skill content.

Prior knowledge in the AI era

Generative AI has made prior knowledge a central design consideration rather than a background variable:

- **The bypass risk.** Proactive agentic AI that pre-fetches and surfaces content can bypass the retrieval practice that activates prior knowledge — the learner never has to recall or integrate what they know before receiving an answer. This is one of the six pedagogical risks identified in the

agentic-education best-practice framework, and it connects directly to Over-Reliance and the Desirable Difficulties principle that effortful processing supports durable learning.

- **Prior knowledge shapes the pattern of offloading, not only outcomes.** In a synthesis-writing study the high-knowledge, minimal-offloading cluster authored 80% of its essay against 2% for the heaviest offloading cluster (mean 25.1 prompts), so prompt volume tracked prior knowledge rather than effort (Poquet et al. (2026)).
- **The benefit gap compounds.** Because productive AI use depends on what a learner already knows, students with stronger prior knowledge leverage it better while novices are the most likely to treat it as a substitute — a distributional risk that can widen achievement gaps even when access is equal (Lodge & Loble (2026)).
- **Priming and activation as design.** GenAI mindtool approaches deliberately "prime the learning task" by activating prior knowledge and curiosity through prompting questions, AI-generated visuals, and analogies (e.g., "What do you already know about ecosystems?") before introducing new content — modeling the retrieval-and-integration path rather than the answer-supply path.
- **Student modeling and memory.** AI systems increasingly model learners' prior-knowledge state and longitudinal memory (e.g., incorporating prior-knowledge state and forgetting curves into tutoring memory), enabling spaced repetition and adaptive review that build on what each learner already knows.(PersonaVLM: Long-Term Personalized Multimodal LLMs)
- **A personalized-adaptation lever.** Because learners differ widely in prior knowledge, adaptation must be tuned to the individual — a core argument for Personalized Learning and adaptive Scaffolding that meet learners at their actual current state rather than a class-average assumption.

Implications for designing AI in education

1. **Activate before you supply.** Design AI interactions to prompt learners to retrieve and articulate what they already know before providing new content or answers — preserving retrieval practice rather than bypassing it.
2. **Model the learner's prior-knowledge state.** Build student modeling and adaptation on estimated prior knowledge (and its misconceptions), not on assumed uniformity, to make personalization genuinely responsive.
3. **Surface and address misconceptions.** When prior knowledge is incorrect, it will interfere; instruction should elicit and correct misconceptions rather than add new content on top of faulty foundations.
4. **Weigh the friction trade-off.** Activating prior knowledge adds desirable difficulty (retrieval, integration) that AI's friction-removing defaults tend to erase — a tension to manage deliberately rather than let automation resolve by default.

Common Misconceptions

"Prior knowledge predicts who does the cognitive work." It predicts outcomes more reliably than it predicts behavior. In a five-day learning-by-teaching study with **23 middle-school tutors**, prior test scores did **not** predict the share of knowledge-building responses a tutor produced, and low-prior tutors worked at

building knowledge rather than defaulting to less. Who engages in the productive struggle is not simply who arrives knowing most.

“Offloading is a stable learner trait, so the same student offloads the same amount everywhere.” It tracks prior knowledge within the task. In a synthesis-writing study the **high-knowledge, minimal-offloading cluster authored 80% of its essay against 2% for the heaviest-offloading cluster**. Offloading is therefore substantially a response to what the learner already has and what the task demands, which makes it a design variable rather than a character one.

“Students with less prior knowledge need more AI support.” That is the direction most likely to widen the gap, since the measured offloading pattern concentrates authorship loss where prior knowledge is thinnest. Support that supplies the work to the learner least equipped to detect the substitution removes the activity that would build the missing knowledge.

“Prior knowledge is a fixed input the course cannot move.” It is the most heavily weighted factor in new learning, which makes building it the highest-leverage task rather than a background condition — the reason domain knowledge is the intervention in its own right, not merely the covariate.

ICAP Framework

> **The ICAP Framework** (Interactive–Constructive–Active–Passive) — a taxonomy of cognitive engagement developed by Michelene Chi that classifies learner behavior into four modes of knowledge change, ordered from least to most cognitively engaged: *passive*, *active*, *constructive*, and *interactive*. In AI in education, ICAP provides both a design target (build tools that elicit constructive and interactive engagement rather than passive consumption) and an evaluation lens (measure whether learners and AI systems are actually engaged at the higher modes).(Systematic review of collaborative learning activities for promoting AI literacy)(Measuring Cognitive Engagement in Collaborative Discourse with an Extended ICAP Framework: Comparing Human Annotation, In-Context Learning, and Reflective LLM Agents)

Questions to Consider

- Think of the last time you 'learned' something by watching a video or reading. The ICAP framework would call that passive. What do you actually retain from passive exposure versus from explaining it to someone else?
- ICAP orders engagement from passive to active to constructive to interactive. Where do AI tools you've used tend to keep learners — and does clicking through adaptive practice count as real engagement or just activity?
- The page argues the most consequential shift is from Active to Constructive — generating explanations or new artifacts rather than just applying knowledge. Why might producing something new be the step that actually changes understanding?
- One study found human experts far outperform AI models at labeling engagement levels. If automated systems systematically underestimate engagement, how should we treat 'engagement' metrics generated by AI?
- ICAP shows that a tool that answers for you keeps you passive, while one that prompts and questions pushes you toward constructive and interactive engagement. Which design choice would you make for your learners?
- The framework is used both as a design target and an evaluation lens. How could you use ICAP in your own teaching or design to tell whether learners are genuinely engaged rather than merely active?

Introduction

ICAP is grounded in the assumption that *what learners do* determines how much and what they learn. Chi's framework posits that as engagement moves from passive to active to constructive to interactive, the nature of knowledge change deepens — from storing, to attending, to integrating new knowledge with prior knowledge, to co-creating knowledge through dialogue. This makes ICAP a powerful analytic tool for AI in education, where the central design question is whether AI assistance supports or displaces learners' cognitive engagement.

The four modes

Mode	Learner behavior	Nature of knowledge change
Interactive	Dialogue with another learner or agent, co-constructing meaning; e.g. defending a position, collaborative problem-solving	Co-creating new knowledge through joint, reciprocal activity
Constructive	Generating new output beyond the given; e.g. self-explaining, comparing, reflecting, drawing	Integrating new information with prior knowledge to produce novel understanding
Active	Manipulating or acting on the material; e.g. taking notes, underlining, pausing to think	Attending to and storing information, sometimes without deep integration
Passive	Receiving information without overt action; e.g. listening to a lecture, reading	Storing information, with limited further processing

ICAP in AI in education

A design target for AI tools

ICAP reframes the central design question for AI in education: an AI tool that *answers for* the learner keeps them in passive/active modes, while a tool that *prompts, questions, and scaffolds* can push learners toward constructive and interactive engagement. This aligns ICAP with Constructivism Pedagogies and Teaching Strategies and with Active Learning research.(Multimodal Learning with Generative AI)(Systematic review of collaborative learning activities for promoting AI literacy)

An evaluation lens for AI agents

ICAP also serves as a measurement framework. In one study, researchers extended ICAP to a 7-point scale to characterize cognitive engagement in collaborative dialogue, then compared trained human annotators with Large Language Models (LLMs)-based labeling (in-context learning, zero-shot prompting, and reflective agents). Human interrater reliability (kappa = 0.906–0.998) far exceeded LLM annotation (kappa = 0.541–0.609), highlighting ICAP's role — and current limits — in automated engagement measurement for Learning Analytics pipelines.(Measuring Cognitive Engagement in Collaborative Discourse with an Extended ICAP Framework: Comparing Human Annotation, In-Context Learning, and Reflective LLM Agents)

Guiding collaborative-dialogue facilitation

Because interactive engagement is the highest ICAP mode, the framework helps locate the value of AI facilitation in online collaborative discussion. Research on LLM facilitation timing shows that *when* an AI intervenes in a discussion shapes whether it supports or interrupts interactive knowledge co-construction — an ICAP-informed caution that autonomous moderation agents need calibration toward human-like restraint rather than over-eager facilitation.

ICAP and learning analytics design

ICAP underlies critiques of shallow "engagement" metrics: interacting with a dashboard by clicking filters is *active*, not *interactive*, engagement. Effective learning-analytics designs elicit Self-Assessment and two-way dialogue rather than merely displaying data — an implication drawn directly from Chi's framework. (Interactive learning dashboards: rethinking learning visualisations as engagement tools)

The Active→Constructive transition as the pivotal step

Although ICAP describes a hierarchy, the most consequential shift for learning is the jump from *Active* to *Constructive* modes (Chi & Boucher, 2023). Active engagement (applying knowledge to similar-but-non-identical scenarios) prepares learners, but it is Constructive engagement — generating explanations, summaries, or new artifacts — that equips them to create new knowledge. This is the crux for AI in education: a tool that keeps learners in the Active mode (e.g., clicking through adaptive practice) may look productive but never pushes them into the constructive generation that yields durable understanding. Collaborative and literacy-focused interventions that deliberately scaffold the Active→Constructive leap tend to show the strongest gains.(Systematic review of collaborative learning activities for promoting AI literacy)

The "strongest gains" part of that claim is an inference from the framework rather than a comparison the review ran. The nine-study review behind it (2015–2023) counts how many interventions *included* each mode (9 passive, 5 active, 7 constructive, 8 interactive), reports no effect size by mode, and notes that no included study relied on a single mode, so nothing in it isolates the Active→Constructive leap (Hingle et al., 2025). The ordering is Chi's; what the review adds is that practitioners combine modes rather than choose one.

ICAP as an adaptive-scaffolding signal in ITS

ICAP's modes can be operationalized as *target states* that an adaptive tutor selects among to scaffold cognitive engagement based on an evolving student model. In a logic ITS, Dey Tithi et al. dynamically chose between an *Active* "Guided" worked-example mode and a *Constructive* "Buggy" example mode. Comparing Bayesian Knowledge Tracing (BKT) against Deep Reinforcement Learning (DRL) and a non-adaptive baseline over 113 students, both adaptive policies improved posttest performance — but in a differentiated way: BKT gave the largest gains to low-prior-knowledge students (helping them catch up), while DRL produced the highest posttest scores among high-prior-knowledge students. This is a concrete demonstration that effectively *personalizing* the ICAP mode of an intelligent tutor depends on modeling the learner's current knowledge — and that no single mode or adaptive method suits every learner. It connects the ICAP hierarchy directly to Adaptive Learning and Knowledge Tracing design.

ICAP as a model of cognitive state for generating human-like agents

Beyond selecting task modes, ICAP has been embedded directly into the *cognitive model* of a generative educational agent. CogEvolution builds an ICAP-based "cognitive depth perceptron" that maps inputs to a probability distribution across the four ICAP levels, fusing this with evolutionary-inspired state updates and Item Response Theory memory retrieval to simulate a student's cognitive evolution (including transitions

such as confusion → insight). Ablations show that removing the ICAP perception module collapses the agent's ability to distinguish shallow from deep learning — evidence that the ICAP taxonomy can serve as a fine-grained, internal measure of cognitive engagement for student simulation, not merely an external evaluation lens.

ICAP anchors assessment of reflective GenAI interaction

ICAP's emphasis on generative, process-level engagement has been adopted by assessment frameworks that evaluate *how* students learn with generative AI. The DRIVE framework explicitly aligns its core construct — deep reflective interaction with GenAI output — with the kind of generative engagement ICAP identifies as leading to deeper learning, and uses it to distinguish surface consumption from effortful, reflective reworking of AI-generated content. This positions ICAP as a theoretical anchor for designing and measuring meaningful GenAI learning interactions rather than merely tracking usage.

Implications for design and research

1. **Design for the higher modes.** AI tools should prompt learners to generate, explain, and dialogue — constructive and interactive activity — rather than deliver passive content or act as answer machines.(Multimodal Learning with Generative AI)
2. **Engage learners across modes.** Effective AI literacy instruction engages learners at multiple ICAP levels — passive exposure, active manipulation, constructive generation, and interactive dialogue — selecting the mode that fits the learning goal.(Systematic review of collaborative learning activities for promoting AI literacy)
3. **Measure engagement honestly.** ICAP gives researchers and designers a common vocabulary for distinguishing genuine cognitive engagement from mere activity — a corrective to shallow Student Engagement.(Measuring Cognitive Engagement in Collaborative Discourse with an Extended ICAP Framework: Comparing Human Annotation, In-Context Learning, and Reflective LLM Agents)
4. **Watch the human–LLM annotation gap.** If automated systems are used to code engagement, their systematic shortfall relative to trained humans must be accounted for.(Measuring Cognitive Engagement in Collaborative Discourse with an Extended ICAP Framework: Comparing Human Annotation, In-Context Learning, and Reflective LLM Agents)

Common Misconceptions

"ICAP is a taxonomy for labelling activities." It is a design and evaluation lens with an ordering claim: passive, active, constructive and interactive engagement differ in the learning they produce, so "build tools that elicit constructive and interactive engagement rather than passive consumption" is a design target rather than a classification exercise. Labeling a lesson with a mode without changing what students do has not applied the framework.

"Time on task or interaction volume indexes engagement level." Volume counts activity, not mode. Scrolling is active and passive in different senses at once, and a student generating many clicks may still be

receiving rather than constructing. The framework's value is precisely that it distinguishes kinds of engagement that activity metrics lump together.

"An AI tutor automatically produces interactive engagement because it converses." Conversation is the medium rather than the mode. A dialogue where the system supplies every substantive contribution is passive for the learner wearing an interactive interface, which is the same confusion the engagement literature documents between behavioral activity and cognitive investment.

"Higher ICAP modes are always better." They cost more, and the ordering is about learning per unit of the relevant processing rather than about what a lesson should always aim for. Foundational fluency can require active repetition before constructive work is possible; the error is settling there, not passing through.

Misconceptions about AI

> **Misconceptions about AI** — the inaccurate beliefs people hold about what AI systems are, what they do, and what using them means for learning and work. Misconceptions are not a single falsehood but a family of calibration errors that cluster around two core mistakes: misjudging what the model is (authority vs. tool, neutral vs. biased, understanding vs. generating) and misjudging what learning requires (output vs. process). They are held not only by students but also by teachers, administrators, policymakers, and the broader public — and correcting them is a core aim of AI Literacy and Trust Calibration education.

Questions to Consider

- Many people believe an AI chatbot's answer is a verified fact because it sounds confident and fluent. The page calls this the 'authority fallacy.' When you read an AI-generated explanation, how do you decide whether to accept it — and how often do you actually verify it?
- The 'learning-equals-output' misconception is the belief that producing work with AI is the same as having learned it. Have you ever felt you 'learned' something by letting a tool do the drafting? What was actually missing afterward?
- People often assume AI is objective and unbiased. The page calls this the 'neutrality illusion' — models encode biases from training data, which in writing contexts can homogenize ideas across an entire class. Where might bias hide in a tool that feels neutral?
- Misconceptions about academic integrity cluster at two extremes: some students treat AI output as 'not copying a person' and so permissible, while others think any use is cheating. Where do you think the line should fall, and who should decide it?
- A common belief is that one query is enough and that AI output is deterministic — the same question always yields the same answer. The page describes this as the determinism error. How might that misconception lead someone to over-trust a single output?
- Misconceptions are described as stable, plausible, and resistant to correction — much like misconceptions in any domain. If simply telling people the truth rarely changes their minds, how should AI literacy actually be taught?

Introduction

Misconceptions about AI matter because they are the cognitive precursor to the harmful behaviors the knowledge base documents under Over-Reliance and Academic Integrity concerns. People rarely set out to misuse AI; they do so because inaccurate mental models lead them to misplace trust, skip verification, and treat output as understanding. In education these errors shape everything from how students study to how teachers and institutions design curricula, Assessment, and policy.

What AI misconceptions are

A misconception here is not mere ignorance of how a model works — it is an actively held, often self-reinforcing belief that produces systematic errors in how students interact with AI. They are directly analogous to the domain misconceptions studied in learning science: stable, plausible, and resistant to correction until confronted. Correcting them is a core aim of AI Literacy and Trust Calibration education.

Common misconceptions in academic contexts

- **The authority fallacy** — treating Large Language Models (LLMs) output as verified fact rather than a probabilistic completion. Drives uncritical acceptance and the answer-seeking-over-understanding pattern documented in AI-tutoring research, where learners accept a model's answer without checking it against Hallucination Risk.
- **The independent-check illusion** — treating AI feedback as an outside correction when the model mirrors your own reasoning. Users' baseline accuracy was the dominant predictor of final performance, and sycophancy-specific prompting cut positional mimicry (OR = 0.26) but left error propagation untouched, so learner training is not the safeguard (Koyuturk et al. (2026)).
- **Learning-equals-output** — believing that producing work *with* AI is the same as having learned it. This is the exact error behind Over-Reliance: the drafting, recall, and revision processes that build durable knowledge get outsourced.
- **The neutrality illusion** — assuming AI is objective and unbiased. Students often miss that models encode training-data biases and that in Writing contexts this produces idea homogenization across a cohort.
- **The integrity gray zone** — misjudging whether AI use is acceptable. Some students see AI output as "not copying a person" and therefore permissible; others over-correct and think *any* use is cheating. Institutional inconsistency feeds both errors.
- **Anthropomorphism** — believing the model has intent, memory, and understanding of *their* context. This over-trust is especially risky academically, because students may rely on plausible-sounding explanations the model cannot actually ground.
- **The determinism error** — expecting one query to be enough and not realizing output is non-deterministic and prompt-sensitive. Underestimating this produces the "prompting gap," where students mistake shallow results for the tool's ceiling.
- **The detection miscalibration** — underestimating both institutional detection and, more importantly, the self-harm of submitting work they cannot later explain or defend.
- **The efficiency illusion** — treating time saved as pure gain, missing that unexercised foundational skills decay and that novices cannot yet tell good output from bad.
- **The friendliness-safety illusion (children)** — believing a friendly-seeming AI is inherently safe and less likely to spy. Leisten et al. (2026) surveyed 71 children aged 10–16 (Mage = 12.90) and ran six focus groups (n = 36) around the Open Source social robot Blossom, finding foundational AI knowledge rose reliably with age (M = 4.41 of 6; β = 0.17) while safety attitudes stayed ambivalent (importance M = 2.51, current safety M = 2.77 on a 1–4 scale), captured in a 12–13-year-old's belief that "maybe if they are good friends he doesn't spy so much" — alongside the

belief that AI's knowledge can be deleted at the press of a button, that hacking leads to kidnapping, and that "the wifi radiates into the brain."

The integrity gray zone has a structure, not just two extremes. Interviews with 20 students, together with their chat logs and course documents, found five separate sites where AI policy lives, from faculty intention through formal policy and student self-policy to actual practice, plus 23 distinct rationalizations in six classes (Kim et al., 2026). The rationalizations were ad hoc and post hoc, assembled to explain use that had already happened rather than to guide it. A strict prohibition did not prevent use so much as intensify moral conflict in students who wanted to comply, which puts the correction target in the policy site rather than in the statement of the rule.

Institutional and public AI myths

Misconceptions are not confined to students — they saturate the institutional and public discourse about AI that students inherit. Rudolph et al. (2025) dismantle eight entrenched "myths" that shape higher-education policy and teaching: that AI is genuinely "artificial" (rather than built from exploited human labor), that it is truly "intelligent" and agentic, that it will unproblematically "make the world a better place," that it is "objective and unbiased," that the US holds a sole superpower monopoly, that it will not disrupt the job market, that it "revolutionises higher education," and that teachers can reliably detect AI-generated work. These institutional myths are the upstream source of many student misconceptions documented above — most directly the neutrality illusion ("AI is objective") and the authority fallacy ("AI is intelligent"), and the detection miscalibration that leads students to assume undetectable, unverifiable use is safe. Where students absorb and act on institutionally-repeated myths, correcting them requires confronting not only the learner's belief but the discourse that feeds it.

Why misconceptions matter for learning

Misconceptions translate directly into the behaviors that cause learning harm. The belief that "AI is always right" suppresses verification; the belief that "using AI is learning" suppresses effortful processing; the belief that "it's not cheating" bypasses the metacognitive review that consolidates understanding. In this sense misconceptions are upstream of the AI Misuse and Learning Harm documented across the knowledge base's evidence base.

The belief that using AI is learning is not only held before use; the tool can manufacture it. Kim et al. describe an LLM fallacy in which opaque, fluent, immediate output is misread as evidence of the user's own competence, so perceived and actual capability diverge by a margin they call ΔC. Because the mechanism is fluency and attribution ambiguity rather than error, the fallacy persists whether the model is accurate or hallucinating, which means a correct AI-assisted answer is not evidence that the belief has been corrected.

Misconceptions beyond students: teachers, institutions, and the public

AI misconceptions are not confined to learners — they are pervasive among the adults who shape education:

- **Teachers and faculty** may overestimate AI's ability to reliably grade or detect misuse, or underestimate its bias, leading to either uncritical adoption or reflexive banning. That assumption of reliability is partly testable and partly false: Humble (2026) red-teamed an everyday AI grading

workflow and found that instructions hidden inside a submitted file raised a failing essay's grade with no visible warning, in 9 of 9 iterations for one strategy and 17 of 18 for another. When teachers hold the authority fallacy about AI outputs, they model the same uncritical posture they should be correcting in students. Preparing educators with accurate mental models of AI is a prerequisite for responsible AI integration and safe pedagogy.

- **Administrators and policymakers** inherit and propagate institutional myths — that AI is "objective," that it will "revolutionise" education, or that detection tools are trustworthy — which then shape policy, procurement, and assessment rules. The trust students develop is partly a product of the institutional framing they inherit.
- **The general public** absorbs media and vendor narratives about AI's capabilities and risks. Because students learn within this discourse, public myths become the substrate from which student misconceptions grow. Correcting AI misconceptions is therefore an AI Literacy task aimed at the whole educational ecosystem, not only at learners.

This breadth is why the knowledge base treats misconceptions as a cross-cutting foundational theme rather than a purely student-facing one: the same calibration errors recur across learners, teachers, institutions, and the public, and correcting them requires confronting both individual beliefs and the discourse that feeds them.

Teachers' pedagogical misconceptions are the mirror image of this: not misunderstandings about AI, but evidence-unsupported beliefs about teaching that persist regardless of AI. Miranda and Calvani (2026) instrument this with the Effective Teaching Questionnaire, where 50 binary items map onto meta-analytic effect sizes ($d \geq 0.40$) so a teacher's answer can be compared against an evidence-aligned benchmark — and their finding is that the misconceptions are deep and specific. A pilot with 123 educators in Italy found the sharpest disagreement on the learning-styles claim (78% of teachers defended visual/auditory matching), then on inclusion and group work (68%) and EdTech overload (54%); average alignment ran near 50% across the planning, cognitive, evaluative and management dimensions. Two details matter for correction design. First, the misconceptions survive university education and teaching practice — the authors describe an "internalized common sense" that "precedes entry into school" and persists — so they are not knowledge gaps a lecture closes. Second, when a conversational AI re-introduced the same items only after validating the teacher's own context, 41% of objections cited genuine contextual limits — class sizes, students with special needs, curriculum coverage — rather than the evidence itself. A further 5.9% called the system "an algorithmic dogma machine": the boundary condition where normative framing breeds defensiveness instead of reflection. For Teacher AI Competency development the implication is that diagnostic-plus-dialogue can surface which beliefs are evidence-based disagreement and which are misconception, a distinction a score alone cannot make.

Correcting misconceptions

Correction is not a one-time disclosure but an ongoing AI Literacy process that develops Metacognition and Self-Regulated Learning: helping students (and the adults around them) monitor their reliance, calibrate when to trust and when to question a model, and see the cost of bypassing their own cognitive work. Because misconceptions are resistant, they are best addressed through direct confrontation with evidence — including the finding that students often *do not perceive* the learning harm of AI misuse.

Refutation text is a core correction technique. Because misconceptions are actively held and resistant, the most direct evidence-based strategy is the refutation text — an instructional text that states the misconception, explicitly refutes it, and presents the correct conception. This is the same family of technique used to correct the domain misconceptions studied in learning science, applied here to students' beliefs about AI itself. The knowledge base's Refutation Text concept page synthesizes how this plays out in AI in education in three complementary ways:

- **AI as the corrector.** Conversational AI tutors can deliver *personalized* refutation, adapting the refutation to a learner's specific misconception on the fly. Corbett & Tangen (2026) found personalized AI dialogue produced larger and faster belief reductions than static textbook-style refutation, with higher engagement and confidence — though the advantage faded by two months without reinforcement.
- **AI as the generator of refutation content.** Akdoğan (2025) found AI-generated conceptual-change/refutation text matched expert-written quality (and both outperformed a prompted interactive dialogue in that science context), showing AI can produce effective correction materials at scale.
- **AI-generated misconceptions as a learning resource.** Rather than treating AI-generated misconceptions as merely harmful, Cheah et al. (2026) propose generating misconceptions and addressing them through structured peer discussion — a collaborative form of refutation that promotes conceptual change and critical thinking.

For misconceptions about AI, this means correction should combine **direct confrontation** (refutation-style materials that name and rebut specific myths) with **scaffolded practice** — using AI Literacy instruction and Metacognition to help people see both the false belief and the correct model. The evidence cautions that the *format* matters: personalized, interactive correction is more engaging and initially more effective, but needs reinforcement to persist; and the outcome measured (knowledge vs. attitudes vs. skills) shapes how large a correction effect appears. Because misconceptions span learners and the adults who shape learning, effective correction must reach teachers, administrators, and policymakers as much as students.

Bernstein and Sibia (2026) show that GenAI-generated analogies introduce structural misconceptions that only source-domain knowledge can catch (Flawed but Memorable: Student Critical Reception of Interest-Personalized GenAI Analogies in Computing Education): a circular-route analogy for a linked list implies a loop back to the start, and a badminton-rally analogy for recursion carries no guaranteed shrinking input. Students who knew the source domain identified these flaws and proposed repairs, while participants noted that a flawed analogy may still be memorable — indicating that a familiar analogy source can help learners detect, rather than absorb, an AI-produced misconception, and that framing flaws as deliberate artifacts for critique turns the risk into an assessment opportunity.

Model-generated misconceptions are a measurable capability, not an accident. Miličević et al. (2026) built SocraticTrap-CS, which prompted seven open-weight models to write a "Socratic trap" for 35 core CS concepts — an explanation that is fluent and authoritative while resting on a subtle, domain-specific error. Of 241 prompted segments, 221 (91.7%) were confirmed as strategic misconceptions by expert majority vote (Fleiss' $\kappa = 0.9487$), with no significant differences between CS domains; 66.5% of the confirmed errors were conceptual rather than factual and none were purely logical. Fluency is the mechanism rather than a defense: persuasiveness averaged 3.71 on a five-point scale and was strongly model-dependent, and

frequency and severity dissociated, with the two models that produced traps most often also rated most convincing. Because a student's poorly framed question can itself act as an adversarial prompt, the authors treat the rate as a capability under adversarial prompting rather than a base rate for ordinary study sessions — and argue the AI Literacy task shifts from fact-checking individual statements to conceptual verification and mental-model validation. This is the darker face of the generative use above: the same capability that can seed productive peer discussion can also entrench an error a learner was already forming.

Refutation-style corrections for common AI misconceptions

Because misconceptions are actively held and resistant, the most direct way to address them — including on this page — is the Refutation Text structure: **name the misconception, explicitly refute it, and state the correct conception.** The entries below apply that structure to the most consequential misconceptions about AI and about learning, teaching, and education:

"AI is always right." *That's a misconception.* AI output is a probabilistic completion, not a verified fact. *The correction:* LLMs generate plausible-sounding text based on statistical patterns; they can hallucinate, be biased, and be confidently wrong. Treat output as a draft to be checked against sources, not an authority to be accepted. This is the core of Trust Calibration and why "always verify" beats "always trust."

"Using AI is learning." *That's a misconception.* Producing work *with* AI is not the same as acquiring the knowledge or skill the work is supposed to demonstrate. *The correction:* durable learning happens through the effortful processes of drafting, recalling, revising, and metacognitively reviewing — exactly the processes that offloading to AI short-circuits. Use AI as a tool alongside that effort, not a replacement for it.

"AI is neutral and objective." *That's a misconception.* Models inherit the biases, gaps, and perspectives of their training data. *The correction:* AI can reproduce and amplify bias; treat its outputs with the same source-critical scrutiny you would apply to any other text. Awareness of this is part of AI Literacy and helps counteract the equity harms of uncritical adoption.

"AI will replace teachers." *That's a misconception.* AI augments but does not displace the pedagogical work of teachers — judgment, contextualization, and the relational and ethical dimensions of teaching. *The correction:* AI increases the need for pedagogical mediation and critical judgment; teachers who understand AI become more effective, not obsolete. This reframing matters because it shapes whether institutions invest in teacher AI competency or reflexively resist or over-adopt.

"AI understands like a person." *That's a misconception.* Models have no intent, memory of you, or genuine understanding of your context. *The correction:* anthropomorphizing AI leads to over-trust and reliance on explanations the model cannot actually ground. Keep the boundary clear: AI is a powerful tool, not a mind.

"AI will transform education automatically." *That's a misconception.* Technology alone does not change learning; it is the pedagogy around it that does. *The correction:* AI's benefits depend on intentional instructional design, teacher preparation, and institutional support — not on simply deploying the tool. This is why evidence and rigorous evaluation matter, and why the knowledge base frames responsible AI use as a AI Governance and policy question rather than a purely technical one.

"One prompt should give me the answer." *That's a misconception.* Output is non-deterministic and prompt-sensitive. *The correction:* expect to iterate, refine, and cross-check; the "prompting gap" —

mistaking shallow first results for the tool's ceiling — is a skill problem, not a tool limit. Developing this is part of Prompt Engineering.

"It's not cheating if a person didn't write it." *That's a misconception.* Academic integrity is about the honest, attributable production of work, not just about not copying a person. *The correction:* undisclosed AI-generated submission can violate Academic Integrity even when no human was copied; the question is whether the work is genuinely the learner's. When in doubt, disclose and check your institution's policy.

These refutations are deliberately written in the Refutation Text form so they can themselves be used (or adapted into interactive AI dialogue) to confront and correct misconceptions about AI — and about learning, teaching, and education more broadly.

Common Misconceptions

- **"Teachers' misconceptions are correctable by presenting evidence."** In a pilot with **123 Italian educators**, disagreement clustered hardest on **cognitive learning styles (78% of teachers defended visual/auditory matching)**, inclusion and group work (68%) and EdTech overload (54%). The strongest disagreements were the ones most resistant to evidence, which is why refutation beats assertion.
- **"Teacher objections to evidence are all resistance."** When the same items were delivered through a conversational AI that **validated the teacher's context before re-introducing the evidence**, **41% of objections concerned real contextual constraints** — class size, special needs, curriculum demands. A substantial share of apparent misconception was accurate objection.
- **"Misconceptions can be detected reliably from dialogue." Of 241 prompted segments, 221 (91.7%) were confirmed as strategic misconceptions by expert majority vote (Fleiss' κ = 0.9487)**, with **no significant differences** between groups. High reliability is achievable under expert adjudication, and that is the condition the claim depends on.

Connected FAQs

- How Can We Address Common Misconceptions About AI in Education?

Refutation Text

> **Refutation text** — a misconception-correction technique in which a text explicitly states a common misconception, directly refutes it, and then presents the scientifically correct conception. Originating in the conceptual-change literature of science education, refutation texts are a proven, low-tech intervention for dislodging stable, intuition-aligned misconceptions that resist ordinary instruction. In AI in education, refutation texts are increasingly used in two ways: as a **comparison condition** for AI-based interventions (personalized dialogue, Large Language Models (LLMs)-generated content), and as **AI-generated content** — conceptual-change texts and misconception texts produced by generative AI to correct beliefs or to seed collaborative discussion.

Questions to Consider

- Have you ever ‘corrected’ a student’s wrong idea by simply presenting the right answer, only to have the misconception resurface later? The page argues misconceptions aren’t gaps but actively held beliefs that resist ordinary instruction. What does that reframe about why your correction failed?
- A refutation text states the misconception explicitly, refutes it, and offers the correct conception — unlike a standard expository text that just presents the truth. Why would naming the wrong idea out loud help change it, when teaching only the right idea apparently doesn’t?
- The research is mixed on whether personalized AI dialogue beats static refutation text: in one study interactive dialogue produced larger, faster belief change; in another, well-crafted texts outperformed a prompted AI chat. What might explain these contradictory results, and what does it tell you about ‘interactivity is always better’?
- AI can now generate effective refutation texts that match expert-written quality, and even generate misconceptions to seed structured peer discussion. Does the idea of deliberately teaching from AI-generated wrong ideas feel risky or productive to you — and under what conditions would you try it?
- Refutation effects appear concentrated among high-achieving students and moderated by epistemology and Metacognition. If the technique helps the strong most, what obligations does that create for an instructor using it with a mixed classroom?
- Before you read further, name one misconception you currently hold about a subject you teach, and imagine writing the explicit ‘wrong’ claim and its refutation yourself. What did that exercise reveal about how hard good refutation is to write?

Introduction

The concept

Refutation texts rest on the idea that misconceptions are not mere gaps in knowledge but actively held, plausible, self-reinforcing beliefs that resist correction — a claim central to conceptual-change research. A

refutation text works by making the misconception explicit, naming it as wrong and explaining why, and then offering the correct conception in a way the learner can integrate. This differs from a standard expository text, which simply presents correct information and assumes the misconception will be displaced.

In AI in education, the core finding is that the *format* and *interactivity* of the correction matter. Converging evidence (Corbett & Tangen 2026) shows that static textbook-style refutation reliably corrects beliefs but that **personalized, interactive AI dialogue** can produce larger and faster belief reduction by targeting the learner's specific misconception and engaging them motivationally. However, this advantage may be context- and design-dependent: in science education (Akdoğan 2025), well-structured conceptual-change texts (expert *or* AI-generated) outperformed a prompted interactive ChatGPT dialogue — suggesting that the dialogue's design (personalized vs. generic) and the domain shape which format wins.

Why refutation text matters for AI in education

- **AI as the corrector.** Conversational AI tutors can deliver *personalized* refutation — adapting the refutation to the learner's specific misconception on the fly, which pre-written texts cannot do. This produces stronger immediate belief change and higher engagement/confidence than static refutation (Corbett & Tangen 2026), though effects may need spaced reinforcement to persist.
- **AI as the generator of refutation content.** Generative AI can produce effective conceptual-change texts that match expert-written quality (Akdoğan 2025), and can generate large numbers of context-specific misconception texts cheaply — scaling misconception-based learning that would otherwise depend on educator experience (Cheah et al. 2026).
- **AI-generated misconceptions as a learning resource.** Rather than viewing AI-generated misconceptions as harmful, structured peer discussion of them — a form of collaborative refutation — can promote conceptual change and critical thinking (Cheah et al. 2026).
- **Complementing misconception education.** Refutation texts are a recommended strategy for correcting the conceptual misconceptions that underpin students' mistaken beliefs about AI itself (see Misconceptions about AI and GenAI knowledge, epistemic orientation, and intellectual values predict undergraduate students' critical GenAI use).

Refutation text vs. related techniques

Refutation texts are one member of the conceptual-change toolkit, alongside analogies, discrepant events, and interactive dialogue. Their advantage is that they are **scalable, low-cost, and demonstrably effective**; their limitation is that static texts cannot adapt to the learner. AI dialogue addresses the adaptation gap but introduces design-dependence (personalization, prompt quality) and, in some studies, no advantage over well-crafted text. The relationship between refutation text and AI dialogue is thus complementary: text offers reliable baseline correction at scale; personalized AI dialogue offers stronger, faster, more motivating correction when well designed.

The two studies behind that design-dependence differ in more than domain. Corbett and Tangen randomized 375 adults aged 19 to 78 and targeted each participant's own highest-rated misconception in a single three-round dialogue; the dialogue's advantage over textbook refutation held at 10 days but had converged by two months (Corbett and Tangen, 2026). Akdoğan's 413 tenth-graders in Ankara received one scripted prompt session rather than a personalized one, and the interactive condition showed no advantage over control while

both expert-written and AI-generated texts did (Akdoğan, 2025). Personalization and retention window, not interactivity as such, separate the results, and the decay curve is the practical finding: one dialogue buys weeks of correction, not durable belief change.

Key research themes

- Whether personalized AI dialogue outperforms static refutation text, and under what conditions.
- Whether AI-generated refutation/conceptual-change text matches expert-written quality.
- Using AI to generate misconceptions for collaborative, misconception-based learning.
- The role of learner characteristics (achievement, epistemology, metacognition) in moderating refutation effectiveness.
- Spaced reinforcement to sustain the initial advantages of interactive refutation.

Practical implications

For educators, refutation texts remain a reliable, low-barrier way to correct stubborn misconceptions. For those integrating AI, the evidence suggests: (1) use AI to *generate* effective refutation/conceptual-change content at scale; (2) where feasible, deliver refutation through personalized AI dialogue for stronger immediate engagement and belief change. Then (3) expect AI-generated misconceptions to be pedagogically useful when structured discussion is used to confront them, and (4) design for the learner — gains skew toward stronger students and depend on epistemology and metacognition, so Scaffolding and follow-up matter.

Common Misconceptions

“Correcting a misconception means presenting the correct answer.” If it did, misconceptions would not survive instruction, and they routinely do. Misconceptions are not gaps but actively held beliefs that resist ordinary instruction: a learner who already has a working explanation does not receive the new one as a replacement, they receive it as a competing claim, and often discard the less familiar one.

“Refutation text is simply writing ‘this is wrong’ before the correct information.” The structure matters — the misconception must be stated as the learner holds it, engaged directly, and only then displaced. A bare correction names a belief the learner may reject as a straw version of their own, which is why the refutation must reproduce their intuition rather than the tidy version of it.

“More information about the correct conception fixes the resistance.” Volume of correct information is the intervention that already fails. Conceptual change requires the learner’s existing model to be made explicit and found insufficient, which is a different instructional move from adding evidence.

“Misconceptions and ordinary ignorance need the same remedy.” They need different ones: ignorance is addressed by supplying knowledge, and a misconception must be unseated first. Treating the second as the first is why a well-explained lesson can leave a student’s original model intact.

Activity Theory

> **Activity theory** (Cultural-Historical Activity Theory, CHAT) — a Vygotskian framework that analyzes learning and work as *tool-mediated, object-oriented, collective activity systems* composed of subject, object, tools/mediating artifacts, community, rules, and division of labor. In AI in education, activity theory is used both as an **analytic lens** (to understand how AI reshapes the activity systems of teaching, learning, and research) and as a **design tool** (to diagnose systemic contradictions and redesign interventions). It frames AI systems — generative AI included — as *mediating artifacts* that reconfigure the division of labor, rules, and community of educational activity, for better and worse.

Questions to Consider

- Activity theory sees learning not as individual cognition but as a collective system of subject, tools, rules, community, and division of labor. If you bring a new AI tool into a classroom, which of these do you expect to change — and which to stay stubbornly the same?
- A key idea is that contradictions within an activity system are the driving force of development, not bugs to be eliminated. Can you think of a tension in your own work or study that actually pushed you to change how you did things?
- Activity theory reframes a teacher's adoption of AI as a property of the whole system — norms, rules, workload distribution — rather than just individual attitudes. What systemic reasons might explain why a capable teacher resists a genuinely good AI tool?
- When AI takes over tasks, it reconfigures who does what, shifting the division of labor between students, teachers, and tools. What cognitive work in your own context has quietly moved from humans to machines — and who noticed?
- Because each discipline functions as its own activity system, the same AI tool can produce different outcomes across subjects. Why might a tool that transforms writing classes barely change a math class, or vice versa?
- Activity theory is used both to analyze how AI reshapes teaching and to design interventions that fix the tensions it exposes. How might seeing your own teaching or study practice as an activity system change how you diagnose a problem?

Introduction

The concept

Activity theory descends from Vygotsky's and Leontiev's cultural-historical psychology (with later development by Engeström) and is a central strand of the broader sociocultural tradition. Its core claim is that human activity is not reducible to individual cognition or isolated tool use; it is a **collective, object-**

oriented, tool-mediated system. Engeström's canonical model of an activity system comprises six interacting elements:

- **Subject** — the individual or group whose agency is the point of view of the analysis (e.g., a student, a teacher, a department).
- **Object** — the motive or goal toward which activity is directed; the "raw material" that the activity transforms.
- **Tools / mediating artifacts** — the instruments, technologies, signs, and language through which the subject acts on the object.
- **Community** — the group that shares the object and constitutes the social context of the activity.
- **Rules** — the explicit and implicit norms, conventions, and regulations that govern activity.
- **Division of labor** — how tasks, power, and responsibility are distributed across the community.

A defining feature is **contradiction**: activity systems contain historically accumulating structural tensions (within an element, between elements, or between an old and a newly introduced element/tool). Contradictions are not bugs to be eliminated but the *driving force of development* — when aggravated, they prompt participants to question and deviate from established norms, opening the way for expansive transformation (Engeström, 2001).

The tools slot is the one generative AI strains. A 2026 sociocultural essay argues that an Large Language Models (LLMs) both mediates the activity and generates contingent contributions that reshape its trajectory, so calling it a tool understates its influence while calling it a collaborator attributes intentionality, accountability and community membership it does not have (Warschauer, Tate and Ritchie, 2026). Their *mediational agent* sits in the tool position without holding a position in the community, which means the division of labor has to be analyzed around contributions and not only around instruments.

Why activity theory matters for AI in education

AI introduces new **tools/mediating artifacts** into existing educational activity systems, which produces both opportunities and contradictions. Activity theory gives AIED research a vocabulary and method for analyzing these changes:

- **AI as a mediating artifact that reconfigures the division of labor.** AI systems do not simply transmit information; they take over tasks, change who does what, and redistribute cognitive work across humans and machines. Studies use activity theory to examine how AI shifts the division of labor between students, teachers, and tools — e.g., in collaborative writing or tutoring — and what this means for human agency.
- **The labor redistributes faster than the rules change.** A scoping review of 53 HCI studies of LLMs in family education found systems producing materials, structuring dialogue, interpreting context and connecting families to outside knowledge, while parents kept the reviewing, adapting and deciding; verification and repair work went undocumented (Luo et al., 2026). Rules governing participation were mostly anticipated rather than enacted, the mismatch between a new tool and an unchanged rule set that the framework predicts.
- **Analyzing teacher adoption and professional development.** Activity theory reframes teacher uptake of AI as a property of the whole activity system (community norms, rules, division of

labor, institutional expectations) rather than of individual attitudes alone. Quantitative work models the six AT components as measurable constructs predicting teachers' intention to adopt AI; qualitative work documents teachers' sixfold sentiments (unsuitable, impersonal, imperfect, uncertain, assisting, inevitable); and intervention work uses CHAT to diagnose and redesign teacher professional development, treating disengagement as a rational response to need-thwarting systems.

- **Norm change and systemic disruption.** Because AI introduces a new tool into the activity system, it generates contradictions with existing rules and norms. Studies of students' GenAI use show how new implicit rules emerge as students adapt — transforming norms around self-direction, learning objectives, the teacher's role, and Ethics.
- **Anchoring learning analytics and measurement.** Activity theory can ground the *design* of analytics by mapping measurement facets onto activity-system elements. A CHAT-anchored analytics pipeline maps temporal participation, discourse quality, and concept sophistication to CHAT elements to detect early at-risk participation in small discussion-based classes.
- **Disciplinarity and cross-context variation.** Because activity systems are historically and culturally situated, activity theory explains why the same AI tool produces different outcomes across disciplines and contexts — each discipline functioning as an activity system with its own rules, community, and division of labor (e.g., differences in undergraduates' GenAI use and disclosure across academic domains).
- **One tool, two activity systems, uneven penetration.** Among ten mathematics academics analyzed through CHAT, GenAI stayed a peripheral tool in the research activity system while reshaping the teacher's role toward mediator of critical reasoning in teaching, with adoption spreading through student use and peer networks rather than institutional policy (Bakogianni et al., 2026).

Activity theory and related frameworks

Activity theory sits within the sociocultural family and is often paired with, or contrasted against, other frameworks: **distributed cognition** and **situated learning** share its emphasis on context and mediation; **community of inquiry** and **communities of practice** share its collective orientation; and **technology-acceptance** models (e.g., TAM) offer a contrasting, more individual-belief account of adoption that activity theory critiques for flattening the collective and structural dimensions. In AIED research, activity theory is frequently combined with other theories — e.g., paired with Self-Determination Theory in teacher-PD intervention design, or with ecological systems theory in situated-AI-ethics frameworks (Raffaghelli et al., 2026).

Key research themes

- **How AI redistributes the division of labor** in teaching, learning, and research activity systems.
- **Systemic contradictions** as drivers of norm change and expansive transformation in AI-augmented education.
- **Teacher adoption and professional development** as activity-system (not merely individual) phenomena.

- **Disciplinary and cross-cultural variation** in AI use, explained by differences in activity systems.
- **Theory-anchored learning analytics** that ground measurement in activity-system elements.
- **The object of AI-mediated activity** — whether the object of learning shifts from mastery to output, and what that means for learning outcomes.

Practical implications

For designers and educators, activity theory counsels looking beyond the AI tool itself to the whole activity system it enters: the rules that govern acceptable use, the community and its norms, the division of labor between human and machine, and the object/motive of the activity. Sustainable AI integration requires *redesigning the system* — addressing contradictions, updating norms, and rebalancing roles — not merely supplying better tools or individual training. For researchers, activity theory offers a rigorous unit of analysis (the activity system, not the individual) and a method (formative intervention, contradiction analysis) for studying and shaping AI's role in education.

Common Misconceptions

"A teacher's adoption of AI is a question of individual attitude." Activity theory reframes it as a property of the whole activity system — subject, tools, rules, community and division of labor — so resistance is frequently a rational response to a system that has not changed. A teacher who declines a tool that adds work, redistributes their attention badly, or conflicts with departmental norms is reading the system correctly; attitude surveys will record that as a disposition and miss the cause.

"If you change the teacher's beliefs, the practice will follow." The unit of change is larger than the person. Interventions that alter norms, workload distribution and shared rules change practice more reliably than those aimed at individual conviction, because the object of the activity is produced collectively. This also explains why individually enthusiastic adopters revert when their department does not move with them.

"Activity theory is a descriptive lens with no design consequences." It directs design at the contradictions between elements of the system — the tool that conflicts with the rules, the division of labor that conflicts with the object — which is where change is actually levered. A lens that locates contradictions is giving you a place to intervene, not merely a vocabulary.

Retrieval, Spacing and Interleaving

> **Retrieval, spacing and interleaving** — the three concrete study techniques that make practice effortful and, as a result, make what is learned durable. Retrieval practice asks the learner to produce an answer from memory rather than recognize one; spacing distributes that practice across time instead of massing it into one session; interleaving mixes problem types instead of blocking them. What unites them is a shared signature: each lowers performance *during* practice while raising retention *after* it — the performance–learning gap in operational form. They are the workhorses of Cognitive Psychology, and in AI-supported learning they are the specific behaviors that generative AI most easily erases, because an LLM that answers on demand removes the retrieval, flattens the schedule, and smooths away the mixing. This page is the *techniques* page. The principle behind them — Bjork's effort–learning trade-off, why harder practice produces more durable learning — is treated on Desirable Difficulties; this page covers what each technique is, what the corpus's studies measured, and how AI implements or undermines them.

Questions to Consider

- Have you ever re-read a chapter until it felt familiar, then been unable to explain it a week later? What did the re-reading actually give you?
- Retrieval practice means answering from memory *before* checking. When an AI assistant is one keystroke away, what would have to be true about your study routine for that retrieval to still happen?
- Spaced repetition systems schedule review at intervals a learner would not choose. Is a schedule that feels wrong a feature or a bug?
- Interleaving mixes problem types and feels messier than blocking. If the corpus offers almost no direct AI evidence on interleaving, how confident should you be in adopting it — and on what basis would you decide?
- Akgun and Toker (2026) found that students who chatted freely with an AI scored worst, even after the best pretesting. What did the free-chatting condition lack that the structured one had?
- Tsiligkiris (2026) found deeper LLM questioning improved task quality but not recall. What does that tell you about using fluency as evidence of learning?

Introduction

Retrieval practice, spacing and interleaving are usually taught and cited together because they were discovered separately but behave alike: each sacrifices how good practice *looks* in exchange for how much survives. In the knowledge base they appear as instances of the Desirable Difficulties principle, but they are also independently actionable — a reviewer can schedule intervals, a tutor can withhold the answer, a curriculum can mix item types, without invoking the underlying theory. Their operational character is why they are the natural bridge between Cognitive Psychology and AI design, and why the studies below tend to report two outcome measures rather than one: performance during practice, and retention after a delay.

The Testing Effect: Retrieval Practice Beats Re-Reading

Retrieval practice — attempting to recall material rather than re-reading it — strengthens memory more than additional study does, and the corpus treats the finding as settled enough to build on rather than re-litigate. The learning-to-learn scoping review places retrieval practice in the **Tools** layer of its three-layered framework (Dimensions of cognitive and metacognitive skill, Processes of self-regulation, Tools such as retrieval practice), positioning it as a concrete, teachable component of learning-to-learn that is meant to counterbalance GenAI overreliance and protect learner agency.

The most informative test in the corpus is a dissociation. Tsiligkiris (2026) logged 22 postgraduate students' prompt-by-prompt Large Language Models (LLMs) interactions during a neuroeconomics case task and separated *depth* (the proportion of explanation-seeking "why/how/explain" prompts) from volume and pacing. Depth predicted independently marked task quality ($\beta = 6.27$, $p = .006$) but had a null association with immediate post-test recall ($\beta = -0.014$, $p = .728$), with recall gains driven by baseline knowledge instead. The reading the author gives is that elaboration drives comprehension while retrieval drives consolidation — and that in LLM-supported study without explicit retrieval demands, learners can experience high fluency with little need to retrieve anything unaided. That is a retrieval-practice finding stated as an absence: the mechanism was not engaged, so the retention outcome did not move.

Retrieval practice is not a universal lever, and the corpus says so. Rachatasumrit, Koedinger and Carvalho (2025) ran a 2×2 experiment with 95 participants crossing knowledge content (verbatim facts vs. generalizable skills, geometry-area materials) with training schedule. They found a content–treatment interaction ($\beta = 0.41$, $p = .038$, $d = 0.38$): pure practice testing produced higher learning gains for **facts**, while example-integrated practice produced higher gains for **skills**. The authors also note that retrieval-practice gains frequently fail to extend to unfamiliar problems. So retrieval practice is strongest where the target is memory for specific content, and it needs to be paired with worked examples where the target is a generalizable skill — which is also why their AI design implication is that Intelligent Tutoring should adapt the example-to-practice ratio to the knowledge component being learned.

The same logic runs through the cheating-sheet study: Chen, Sakhnini and Istead treat *constructing* a cheat sheet as an active, generative study strategy (selection, condensation, organization) rather than logistics, and frame the AI-era risk as offloading the artifact's construction and losing the metacognitive rehearsal that building it provided.

Spacing and Distributed Practice

The spacing effect — that the same total practice produces more durable learning when distributed across sessions than massed into one — is the most algorithmically exploited of the three techniques, and the corpus's applied systems are built around it.

Memdora is the clearest example of spacing treated as an engineering problem. It grounds scheduling in the Ebbinghaus forgetting curve, cites the figure that roughly **70% of newly learned material is forgotten within 24 hours** without review, and integrates **FSRS-6**, described as the current state-of-the-art spaced-repetition algorithm. Its argument is that scheduling alone is not enough: existing tools reduce flashcard interaction to a single binary gesture, "flip and self-rate", which the authors call an impoverished model that fails to exploit cognitive-science evidence on retrieval practice. Memdora's contribution is therefore a

taxonomy of 17 cognitively-grounded interaction types across Language, By Heart and Exam categories, each mapped to peer-reviewed evidence displayed on the card, plus an effort-based reward system that compensates actual cognitive engagement rather than app presence, a unified generation pipeline that creates cards at the point of reading, and a classroom layer that reports learning outcomes at the individual card level.

Malhotra's (2026) bilingual lecture companion attacks that authoring cost from the other end: it transcribes English–Hindi lectures in the browser and generates flashcards on-device, built for Indian classrooms where UDISE+ data put internet access at about 54% of schools.

Akgun and Toker (2026) supply the corpus's strongest experimental evidence on how spacing is *structured*. In a three-arm randomized study of 89 undergraduates in an applied statistics course, all three groups practiced in spaced sessions with identical number and timing over seven weeks; only the interaction structure differed. Adaptive spaced retrieval (G1) reached the highest posttest score (M = 78.19) and the highest observed practice effort (M = 0.85); fixed spaced retrieval (G2) followed (M = 74.55, effort 0.74); learner-directed AI study with no enforced retrieval came last on both (M = 67.28, effort 0.49). The multivariate effect was significant (Wilks' $\Lambda = .664$, partial $\eta^2 = .185$), with G1 ahead of G3 on retention at $d = 0.92$ ($p = .003$). The detail that matters pedagogically is that G1's agent was configured to *withhold*: response-contingent probes for Misconceptions about AI, requests for elaboration after superficial answers, advancement only on adequate conceptual engagement, and direct solutions explicitly excluded from its allowed outputs. The authors' own reading is that pretesting is a front-loaded catalyst rather than a standalone intervention whose benefits survive open-ended AI access.

A randomized field experiment reports distribution over massed time as the operative dose: weekly mastery tracked completed tutoring weeks rather than engaged minutes, each additional completed week adding 2.00 points of 55 ($p = .018$) (Yang, Van Alstyne and Dellarocas (2026)).

Two further corpus findings sharpen what spacing does and does not yet get right. Schuetze, Yan and Carvalho (2025) fit Knowledge Tracing models to a six-session successive-relearning dataset and found that BKT, BKT-with-Forgetting and the Additive Factors Model reproduce learning trends when fit retrospectively (AUC 0.74–0.79) but, under time-based cross-validation of the kind a deployed tutor would need, overestimate future performance by roughly 58%, 51% and 47% respectively and **fail to capture the spacing effect** — sometimes predicting the opposite ordinal ordering across spacing conditions. In other words, the scheduling decisions made by adaptive systems may be based on models that do not represent the very effect spacing depends on. And LLM student modeling and long-term memory names the design gap directly: most tutoring systems lack longitudinal memory, and how such memory should interact with spaced repetition and forgetting curves remains an open question.

What the corpus does not yet show

Neither applied system has produced retention evidence of its own: the Memdora article reports improved retention relative to traditional spaced-repetition tools, but describes no delayed-interval outcome study behind that claim, and the bilingual lecture companion — which generates flashcards automatically to remove the authoring cost that blocks evidence-based retrieval and spaced practice, while simplifying scheduling to a binary "know it / still learning" rating rather than the graded SM-2 and FSRS algorithms —

states plainly that **no learning-outcomes study has been run**, only a pre-registered protocol. The scheduling machinery is better evidenced than the learning it is meant to produce.

Interleaving

Interleaving — mixing problem or item types within a practice session rather than blocking them by type — is the weakest-evidenced of the three in this corpus, and that should be stated rather than padded. Interleaving appears on Desirable Difficulties only as one instance in a list of effortful conditions, and no study in the knowledge base tests an interleaving manipulation against a blocked control.

What the corpus does contain is adjacent and worth distinguishing carefully. Simulating learner task-selection models **Interleaving** and **Blocking** as two of eight candidate learner strategies in a Mastery Learning Simulation, alongside strength targeting, weakness targeting and outcome-informed rules. The finding there is about choice architecture rather than memory: some learner strategies systematically delay progression through over-practice, and task-selection constraints repaired the maladaptive strategies while leaving Interleaving, Blocking, Strength Targeting and Weakness Targeting at steady over-practice levels. That is evidence that interleaving is a *selectable behavior* a system can accommodate or constrain — not evidence that interleaving improves retention. The remaining mentions in the corpus are unrelated senses of the word (interleaved agent stages in From Confusion to Consolidation: A Staged Conversational Workflow for Post-Lecture Review; interleaved visual-textual solution trajectories in a geometry Benchmark), and they should not be counted as interleaving evidence.

Interleaving's inclusion here therefore rests on the same theoretical family as the other two techniques and on its status in the Cognitive Psychology literature, not on a study in this knowledge base. Treat it as the open slot.

How AI Implements and Undermines These Techniques

Implementation. AI's most defensible contribution is scheduling and generation, the parts of these techniques that are tedious rather than pedagogically interesting. Adaptive scheduling is implemented in Memdora via FSRS-6 and in knowledge-tracing architectures that estimate mastery over time; adaptive *pretesting* is implemented by Akgun and Toker's response-contingent agent, which reads prior-session performance signals to raise conceptual depth in weaker areas while maintaining challenge in stronger ones; automatic flashcard and pretest generation is implemented in the bilingual lecture companion, where card authoring is the cost that blocks spaced practice in the first place. Longitudinal student memory is the architecture that would let any of this persist across semesters, and Woollaston and colleagues (2026) supply the design vocabulary for doing it deliberately: intentional friction, dynamic Scaffolding, human-in-the-loop oversight, and considered rather than maximal AI utilization.

Undermining. The failure mode is specific and documented repeatedly. Woollaston et al. (2026) name the first of their six pedagogical risks as prior-knowledge activation: agents that pre-fetch and surface content **bypass the retrieval practice that activates prior knowledge**, so the learner never recalls or integrates what they know before receiving an answer. Prior Knowledge states the same bypass risk as a general property of generative AI, and adds the design countermeasure — activate before you supply. The fluency illusion is the mechanism on the learner's side: an LLM supplies complete, coherent explanations on

demand, so the learner allocates less effort to internal retrieval and reconstruction while the session *feels* productive, which is precisely the dissociation Tsiligkiris (2026) measured. The three-arm pretesting study makes the same point experimentally: the arm with free AI access and no enforced retrieval performed worst on end-of-semester retention, and interaction volume did not differ significantly across arms, so the gap was produced by structure rather than by how much students engaged.

Preserving retrieval demand. The corpus converges on a small set of design features. The pretesting agent's policy is the most concrete: withhold direct solutions by configuration, probe misconceptions, request elaboration after superficial attempts, and advance only on adequate conceptual engagement. Tsiligkiris recommends embedding retrieval demands *after* LLM use through closed-tool outputs — short-answer questions, concept maps drawn from memory, teach-back explanations without the model — and separating scaffolding from checking, so the model is available for clarification and Feedback but distinct checkpoints require independent recall. KnowLoop shows the teach-back form in a deployed system: a Peer agent scaffolds reflective teach-back that surfaced gaps learners could not articulate, and its participants asked to move fluidly between clarification and consolidation rather than treating them as strict phases. Chen, Sakhnini and Istead add the assessment-side version — value the construction process rather than the artifact — while Schorr and colleagues (2026) position these tools as learnable skills that reduce overreliance and support learner agency. Underneath all of them is the one non-negotiable: something must require the learner to produce an answer that the model has not already given.

Limits of the Evidence

- **Small samples and single contexts.** The pretesting study's analytic sample is 89 undergraduates in one applied statistics course, with 27–34 students per arm; the LLM interaction study has n = 22 with a single-group design that supports no causal claim; the teach-back study has 22 participants. The pretesting authors state that replication across domains and task types is needed for generalizability.
- **Short or absent retention intervals.** The interaction-depth study tested immediate recall only, with no delayed measure, so its null is a null for short-term retention specifically. Memdora's retention advantage and the LLM-depth dissociation alike are not tracked over the weeks that the spacing literature would require; the pretesting study's seven-week window is the longest in the corpus.
- **Self-report and proxy measures.** Practice effort in the pretesting study is a behavioral indicator scored by two raters against a rubric from conversation logs, which the authors explicitly note is not a measure of internal motivational state; the LLM-depth measure is a keyword-based proxy capturing the surface form of explanation-seeking rather than its quality.
- **Instrumentation and modelling limits.** Knowledge Tracing models in the corpus fail exactly where spacing decisions need them, and the authors attribute past successes to retroactive full-dataset fitting rather than deployment-realistic validation. The bilingual companion's flashcard quality is unverified against ground truth, with no automated fact-checking layer, and it has run no outcomes study at all.

- **Interleaving has essentially no direct evidence here.** As stated above, the corpus contains no blocked-versus-interleaved comparison, only a simulation in which Interleaving is one selectable strategy among several.
- **Subject populations and content.** The evidence base concentrates on higher education, on STEM and statistics material, and on fact-versus-skill distinctions from geometry and multiple-regression content; generalization to K-12 settings, to humanities and writing, and to non-Western classrooms is not established by these studies.

Common Misconceptions

"Better AI questioning produces better retention." It produces better work. Tsiligkiris (2026) found deeper LLM questioning improved independently marked task quality (**β = 6.27, p = .006**) while having a **null association with immediate post-test recall (β = −0.014, p = .728)**, with recall gains driven by baseline knowledge instead. The quality of the artifact and the durability of the memory are different outcomes, and better dialogue moves the first without moving the second.

"There is one best practice format." The format depends on what is being learned. A content–treatment interaction (**β = 0.41, p = .038, d = 0.38**) shows **pure practice testing produced higher gains for facts**, while **example-integrated practice produced higher gains for skills**. Prescribing retrieval practice for everything, or worked examples for everything, gets half the material wrong.

"Retrieval practice means quizzing, and any quizzing counts." The mechanism is producing an answer from memory rather than recognising one, which is why a multiple-choice recognition task is a weaker version of the same activity. An AI that generates endless recognition items has generated activity of the right name and the wrong mechanism.

"AI can faithfully deliver these techniques, since they are well specified." It can also quietly defeat them. Spacing requires the system to withhold the material it is most able to supply on demand, and retrieval requires it not to answer — so the technique's effectiveness depends on constraints an agreeable assistant has no incentive to impose.

Learner engagement and experience

Student Engagement

> **Student engagement** — the degree and quality of a learner's active involvement in the learning process, most often decomposed into behavioral, cognitive, and affective dimensions. In AI in Education research, student engagement is both a key outcome (does an AI tool keep students engaged?) and a mechanism (does engagement mediate between AI design and learning?). It is conceptually distinct from learning itself — engagement is participation in learning, not proof of cognitive gain — and from the specific metrics used to measure it.

Questions to Consider

- The page insists engagement is not the same as learning — a student can be behaviorally active (clicking, spending time) while cognitively shallow. Where have you seen high 'engagement' that produced little learning, and how did you notice?
- Think of a moment you were deeply cognitively engaged in something — truly wrestling with an idea. What was different about it compared to times you were merely busy or entertained, and could an AI tool reliably create that state?
- Engagement is broken into behavioral, cognitive, and affective dimensions that can diverge. Why do you think researchers insist on treating these separately rather than as one thing, and what would you measure to tell them apart?
- The research suggests deep cognitive engagement with AI predicts learning, while shallow engagement predicts over-reliance. If a tool is 'engaging' but shallow, who is at fault — the design, the task, or the learner?
- How might an AI tool satisfy autonomy, competence, and relatedness (the needs behind engagement) without those features turning into shallow entertainment that displaces real learning?

Introduction

Engagement is a multidimensional construct rooted in educational psychology. **Behavioral engagement** refers to participation, effort, persistence, and on-task activity. **Cognitive engagement** refers to the depth of mental processing — elaboration, critical analysis, self-AI Regulation in Education, and the investment of mental effort. **Affective engagement** refers to emotional reactions such as interest, enjoyment, anxiety, and identification with learning. These dimensions can diverge: a student may be behaviorally active (clicking, spending time) while cognitively shallow (passively accepting output), or affectively interested while behaviorally distracted. This multidimensionality is why engagement must not be equated with any single observable behavior.

How student engagement appears in the research

- **Engagement as an outcome of AI design:** GenAI motivation research shows that engagement in Generative AI-supported learning follows the satisfaction of basic psychological needs (autonomy, competence, relatedness) — engagement is the downstream result of motivational support, not of technology availability alone. Engagement is often measured by self-report while behavioral engagement comes from interaction logs, and the two are not interchangeable.
- **Engagement gain without a learning gain, in a cluster-randomized classroom trial:** Rücker and Becker-Genschow (2025) randomized 195 ninth-grade classes (experimental group 102 students) to a domain-specific mathematics chatbot or to conventional differentiation materials for a single lesson on the Heron method of estimating square roots. Situational interest rose substantially in the chatbot condition (M = 2.63 vs 2.43, p = 0.00005, Cohen's d = 0.63) and acceptance on all four Technology Acceptance Model dimensions was high, yet the pre-post performance comparison found no significant group-by-time interaction (F(1194) = 2.84, p = 0.094) and extrinsic cognitive load was slightly higher. The study is one of the few cluster-randomized tests of a customized chatbot in secondary mathematics, and its split result is the point: interest and achievement moved on different schedules, so an engagement finding is not evidence of learning.
- **Quality over quantity:** Critical engagement in AI code completion, cognitive-engagement discourse analysis, and scaffolding critical engagement show that *deep* (cognitive) engagement with AI predicts learning, while *shallow* (behavioral) engagement predicts the Over-Reliance and learning displacement that dominate the knowledge base's risk literature.
- **Agentic engagement and AI feedback literacy develop together.** Three waves six weeks apart in 399 undergraduates showed within-person paths in both directions (β = 0.222 and β = 0.263), so engagement is not only an outcome of design but part of what builds the capacity to use feedback (Xu (2026)).
- **Fragile and context-dependent:** Polished artifacts, fragile engagement and multi-institution engagement patterns find engagement varies by task, context, and learner — an AI tool that engages one student deeply may produce shallow, output-chasing behavior in another.
- **Motivational antecedents:** AI availability and motivation shows that knowing AI is available can reduce the perceived value of effortful engagement, particularly for novice learners — engagement is shaped by expectancy, value, and perceived competence as much as by tool features. **Wang & Wang (2026)** extend this with a goal-setting-theory account of **758 university English learners** in AI-assisted learning, showing that **teacher support** directly enhances engagement and operates through students' **mastery-approach and performance-approach goals** (rather than avoidance goals). Engagement in AI contexts is therefore not only an individual or design outcome — it is also **socially scaffolded** by the teacher and by the goal orientations learners are encouraged to adopt.

That Scaffolding has an institutional counterpart with a dual pathway. Chen's (2026) two-study design (160 art students in a scenario experiment, 425 surveyed) found that perceived inconsistency between a university's GAI advocacy and its actual teaching and assessment practices predicted creative process

engagement through two opposing appraisals — negative via hindrance (β = −0.060, p = 0.004) and positive via challenge (β = 0.217, p < 0.001) — with pathways thinking strengthening only the positive route, so the same institutional condition engaged some students and disengaged others.

- **Competency and emotion as engagement drivers:** Zhao et al. (2026) model **871 university students** interacting with an Large Language Models (LLMs) chatbot, finding that **GenAI competency** predicts chatbot engagement both directly and indirectly through **positive emotions** (the affect pathway), and that both competency and positive emotion predict engagement and positive learning emotions. Engagement is thus jointly a *skill* and an *affective* outcome — learners who lack AI competency and experience anxiety or frustration disengage, which has implications for AI Literacy training as an engagement intervention rather than merely a skill goal.
- **Discipline-associated cognitive engagement in student-AI chat.** Chang and Li (2026) show that student prompts to AI encode ~62% higher-order cognitive demand on average, but Bloom-level engagement profiles differ sharply by discipline (STEM Apply-prevalent 20.8%, language Understand-prevalent 31.7%, social science Create-prevalent 33.8%). Using a within-person design, they found the same students produced significantly more higher-order prompts in social science than STEM courses ($p < .001$), with course-level variation exceeding student-level variation — evidence that cognitive engagement with AI is shaped by disciplinary context, not just individual style.
- **AI feedback sustains behavioral activation.** Geschwind et al. (2026)'s semester-long lab-in-the-field experiment found that students receiving individual GPT-4 feedback on open-ended tasks sustained the highest participation across eight weekly tasks (~50% by the last, vs ~30% for lecturer- or peer-feedback groups) and wrote ~29 more characters per answer — individual AI feedback activated engagement on both the extensive margin (participation) and the intensive margin (effort per response), even though students rated the peer feedback slightly higher.
- **Predicting academic AI use from learning constructs.** An exploratory machine learning framework analyzed survey data from 166 university students to identify learning-related constructs associated with intended academic ChatGPT use, using SHAP analysis to maintain interpretability. Findings inform how engagement, learning support, and other constructs shape students' incorporation of AI tools into academic work.
- **Access to an AI tool can *lower* measured engagement, and completion rates will not show it.** Liu et al. (2026) randomized tutor access across 13 blocks at a large U.S. public university and found recorded platform participation fell by 0.90 SDs, page views by 0.37–0.38 SDs and active days by 0.51–0.61 SDs — while homework submission and on-time submission were unaffected. The dissociation is the measurement lesson: a course monitoring only assignment completion would have seen nothing, because the reduction sat in the discussion, quiz and instructor-interaction activity the platform logged. Students in treated sections also reported asking the instructor fewer content questions (about 57% versus 44%), so the decline coincided with substitution away from human contact rather than with disengagement from the course.
- **Reply latency is an engagement lever.** In 1,137 Quantitative AI tutoring sessions, faster replies tracked with more student messages and more correct practice (median reply time 1.9 s to 31.0 s across models; lower latency correlating with engagement at Spearman ρ=-0.81, p=.0056). The

authors read that chain as explaining how models that score unremarkably on teaching quality still reach human-level gains (Northcutt et al. (2026)).

- **AI use can travel with greater class absenteeism while confidence does not predict it.** A PLS-SEM survey of 291 Portuguese university students found general AI use positively associated with absenteeism ($\beta = 0.148$, $f^2 = 0.029$) and with Self-Efficacy for independent learning, yet self-efficacy itself did not predict absenteeism ($\beta = -0.068$, $p = 0.276$) — the paper's "confident but absent" pattern. The attendance association was modest and secondary to peer influence ($\beta = 0.510$, $f^2 = 0.326$) and time management ($\beta = -0.163$), and because the AI-use construct was unidimensional and mixed support-oriented with substitution-oriented items, the study cannot separate complementary from substitutive use or establish direction (Franco et al. (2026)).
- **Engagement, flow and emotional intelligence grew together in AI-assisted music classes.** Five waves across a semester with 850 undergraduates showed mean growth in all three, with slope correlations of 0.39 between engagement and flow and 0.22 between engagement and emotional intelligence; growth in flow carried the link to emotional intelligence (Zhang & Tang, 2026).

Measuring engagement: the metric-choice problem

Engagement is operationalized through a range of observable signals. **Behavioral metrics** measure what learners *do* (time-on-task, activity counts, interaction frequency, persistence); **cognitive metrics** measure how learners *think* (depth of processing, critical engagement, discourse analysis); **affective metrics** measure how learners *feel* (emotion, motivation, interest); and **contextual metrics** capture multitasking and attention. AI-education research increasingly combines these and treats engagement as a mediating mechanism between AI tool design and learning outcomes, rather than an outcome in itself.

- **Six AI application families + multi-method measurement:** Zhou's (2025) systematic review of 24 WoS studies maps six AI applications for engagement — chatbots in course design, emotion/facial/voice recognition and eye tracking, ML for data analysis, teacher–student interaction support, personalized feedback/recommendations, and AI-powered bots in smart learning environments. It finds that integrating multiple AI modalities and data sources yields more accurate, real-time insight into cognitive, emotional, and behavioral engagement than single-source approaches — reinforcing the metric-choice problem above.

The choice of metric is definitional: a study that measures engagement as *time-on-task* may conclude an AI tool enhances engagement when students spend more time interacting with it, while a study that measures engagement as *critical processing* may reach the opposite conclusion for the same tool. This is why the knowledge base's research distinguishes engagement (participation) from learning (actual cognitive gain) — see performance vs. learning — and why engagement metrics must be validated against what they claim to measure.

Self-report and behavioral records of the same use can diverge almost completely. Keith, Wood and Posey (2026) measured AI engagement modes twice in the same 171 students: once with a 29-item self-report instrument, and once by classifying 1,353 transcript turns. No paired profile correlation survived correction at $|r| \geq .30$, mean total-variation distance was .701 and only .002 closer than random re-pairing, and behavioral composition raised explained variance by .166 against .031 for self-report; only observed profiles tracked quiz scores, where explanation-seeking turns accompanied higher scores ($r = .33$, $p < .001$)

(The eight-mode AI engagement typology: Differential cognitive signatures and a self-report–behavior gap). A self-report of how a student engages carried almost no information about how that student actually engaged, which makes the metric-choice warning above a measured result rather than a caution.

- **Engagement as a fragile, situation-dependent signal:** Polished artifacts, fragile engagement and multi-institution engagement patterns find that engagement varies by context, task, and learner — the same tool produces strong engagement for some students and shallow, output-chasing behavior for others.
- **Behavioral telemetry from learning platforms:** Effort and progress forecasting, Learning Engagement Assistant, video engagement assessment, and learning dashboards translate behavioral and physiological signals (attention, activity, persistence) into engagement metrics used for adaptive feedback and instructor intervention.
- **Physiological sensing adds a modality — and a baseline problem.** E3Sense co-locates dry-electrode EEG, eye-tracking glasses, and forehead electrodermal electrodes on the head and predicts 450 segment-level engagement ratings from 30 university participants on a five-level ordinal scale: AdaBoost over the fused Multimodal AI representation reached 75.0% balanced within-one-level accuracy against 63.0% for always predicting the most common rating. The narrowness of that gap is the point — within-one credit hands a sensor-free baseline most of its score on skewed ratings — and asking learners what engagement means to them moved the same measure from 64.6% to 71.5%, evidence that the self-report label, not only the sensor, decides what such analytics can claim.
- **Fairness constraints need held-out subjects to hold.** A multimodal attention estimator's gender-targeted regularizer cut the validation MAE gap from 0.02 to 0.005 but increased both the gap and worst-group error on held-out subjects, so subgroup-aware, repeated subject-level validation belongs in any engagement-sensing claim (Fragkiadakis et al. (2026)).
- **Engagement as a learner-modeling signal:** Engagement intensity as a learner-modeling signal uses engagement strength to inform adaptive AI systems, positioning engagement metrics as inputs to Learner Modeling and Adaptive Instruction and Adaptive Learning rather than merely evaluation outputs.

Engagement vs. learning

A central theme in the knowledge base's research is that engagement and learning must be distinguished. AI tools that generate high engagement (time on task, interaction volume) may not produce learning if that engagement is passive or substitutes for the cognitive work of understanding — see performance vs. learning. Conversely, productive struggle and desirable difficulty can produce learning even when surface engagement feels lower. Engagement is therefore best treated as a *mechanism* — valuable insofar as it reflects or enables meaningful cognitive processing — rather than a terminal outcome.

The distinction is not academic. Pramod and Patil (2026) place engagement at the center of their PLS-SEM model, between motivation and social presence on one side and *perceived* performance on the other — the largest coefficient in their model, and still a perception rather than a measure of learning.

Pedagogy mediates AI's effect on engagement

A systematic synthesis of AI in higher education (Long et al., 2026) emphasizes that the **teaching method an AI tool is embedded in is the decisive mediator** of whether it engages students. Chatbots, adaptive systems, and predictive analytics enhance engagement most when deployed within interactive pedagogies — flipped classrooms, project-based learning, and scaffolded feedback loops — rather than as standalone tools. The review formalizes this as the **PMAISE model** (Pedagogical Mediation of AI for Student Engagement), mapping the alignment between AI technologies, pedagogical strategies, and the affective, behavioral, and cognitive dimensions of engagement. The implication is that engagement outcomes are co-produced by the tool *and* the surrounding instructional design: the same AI can amplify engagement in one pedagogy and inhibit it in another.

A two-dimensional account makes the same point from the instructional side. Al Nafjan's Rigor–Commitment Alignment Framework treats engagement under GenAI as jointly determined by how demanding the task is and how committed the teacher is to students' learning, and it predicts four configurations (Rigor, commitment, and generative AI: a conceptual framework for student engagement in EAP writing). Weak rigor with weak commitment (Neglectful) and weak rigor with strong commitment (Indulgent) both settle into surface use, since nothing obliges the student to evaluate or justify what the tool produced. High rigor with thin support (Punitive) is predicted to push students toward concealment rather than responsible use, and only high rigor with high support is predicted to yield deep, agentic engagement.

The framework's load-bearing claim is amplification rather than causation. Differences between the four configurations should widen as GenAI becomes readily available, as assessment rewards the final product, and as composing processes stay invisible, so the tool magnifies conditions the task and the teacher already set instead of creating engagement patterns on its own. Al Nafjan states that the framework is propositional and untested, which makes the four profiles expectations awaiting empirical test rather than observed effects.

Connections to related concepts

Student engagement connects to Motivation and Self-Determination Theory as its psychological drivers, and to Student Experience as the lived context. Its measurement relies on Learning Analytics and Educational Measurement, which supply the quantitative tools for operationalizing the dimensions above. The distinction between deep and shallow engagement ties directly to Self-Regulated Learning (self-regulated learners engage strategically), Cognitive Offloading and Over-Reliance (shallow reliance as the failure mode), and Metacognition. In system design, engagement signals feed Learner Modeling and Adaptive Instruction and Adaptive Learning, and engagement outcomes feature in Research Methods in AIED evaluations of AI-education interventions.

- **Learner characteristics moderate TTS dialogue-based lessons (2026):** In LLM+TTS-generated teacher–student, student–student, and teacher–teacher dialogue lessons, Experiential Learning style and critical-thinking disposition significantly interacted with dialogue format for ARCS-based motivation, indicating that AI-generated dialogue content is differentially motivating depending on learner profile (Interaction Effects Between Learner Characteristics and Dialogue Format in TTS Dialogue-Based Lessons).

- **Dimension-specific gains at the primary level (2026):** A nine-week GenAI-supported L2 writing program with 301 Grade 5 and 6 students raised behavioral and emotional engagement but left cognitive and metacognitive engagement unchanged, and its authors name reduced self-monitoring during writing as a standing risk (Lu et al., 2026). The pattern is a concrete instance of the engagement-versus-learning distinction above: more activity and more enjoyment did not translate into deeper processing.
- **The dissociation can run the other way (2026):** In a 12-week vocational interior-design course, an immersive VR studio with an embedded LLM teaching assistant raised cognitive (d = 0.90) and behavioral (d = 0.75) engagement over traditional project-based instruction while affective engagement did not differ significantly (d = 0.38) — the inverse of the L2 writing case above (Jin et al., 2026). Cognitive and behavioral gains here came with *lower* reported cognitive load, which the authors attribute to the assistant absorbing search and cross-disciplinary integration effort. Read against the writing case, the two studies suggest that which engagement dimension an AI-supported intervention moves is a property of the design — discourse-heavy immersive collaboration versus solo writing support — rather than of AI assistance in general, and that an affective advantage cannot be assumed from high-fidelity or intelligent feedback.
- **AI literacy works on engagement through psychological resources (2026):** A moderated mediation study of 1,198 undergraduates in Zhengzhou, China (Wang, 2026) modeled engagement as an outcome of AI Literacy rather than a by-product of tool use. AI literacy predicted learning engagement directly and also indirectly by building psychological capital, with the indirect route carrying roughly half of the total effect — partial mediation, so a technological competency converts into engagement only partly through the psychological resources it generates. Professional commitment, an identity-based variable, moderated the psychological-capital-to-engagement link without any direct effect of its own, and the translation of psychological capital into engagement was markedly stronger for students who saw themselves as headed into the profession. The pattern is the clearest available instance of the point above that learner characteristics condition how AI affects engagement.
- **AI pre-class practice can raise live participation (2026):** A preregistered field experiment with 759 MBA students found that preparing with a voice-based AI discussion partner raised voluntary contributions by about 31% in later sessions, but only after a second use; a first use preceded lower participation (Wang et al., 2026).
- **Disengagement as a turn-level move, not a stable state:** Rho et al. (2026) coded 5,522 student utterances to an AI teachable agent in Math Nation into six conversational-disengagement categories (False Answering, Mocking, Ghosting, Mirroring, Withholding, Random/Noisy) and found the engagement rate dominated at 75.7% of utterances. The prevalence-based associations of False Answering and Mocking with post-test scores did not survive a human-annotated sensitivity check. The sequential analysis is the engagement-relevant result: the highest-performing cluster combined moderate disengagement with strong recovery-to-engagement transitions (Withholding → Engagement p = 0.83), while the lowest showed persistent self-loops without recovery (Engagement self-loop p = 0.96). Withholding was the one disengagement type that tended to persist rather than resolve — persistence versus repair, not presence versus absence, is the distinction that separates engagement trajectories.

Common Misconceptions

“If engagement went up, learning went up.” This is the single most costly inference in the AI-engagement literature, and the knowledge base contains a clean counterexample. Rücker and Becker-Genschow (2025) randomized 195 ninth-grade classes to a domain-specific mathematics chatbot or conventional differentiation materials for one lesson on the Heron method. Situational interest rose substantially in the chatbot condition ($M = 2.63$ vs 2.43, $p = 0.00005$, Cohen’s $d = 0.63$) and acceptance was high on all four Technology Acceptance Model dimensions — yet the pre-post performance comparison found **no significant group-by-time interaction** ($F(1194) = 2.84$, $p = 0.094$), and extrinsic cognitive load was slightly higher. Interest and achievement moved on different schedules. An engagement finding is not evidence of learning.

“Engagement is one thing, and time-on-task measures it.” The construct is multidimensional and its dimensions diverge by design: a student can be behaviorally active — clicking, accumulating time — while cognitively shallow, passively accepting output. Self-report and interaction-log measures of the construct are not interchangeable, which is why a claim about “engagement” is uninterpretable until the dimension and the instrument are named.

“More behavioral activity means deeper engagement.” Often the reverse. Deep cognitive engagement with AI predicts learning, while shallow behavioral engagement predicts the over-reliance and learning displacement that dominate the risk literature; polished artifacts are the canonical case, where a clean output signals activity while the thinking did not happen. Busy interaction logs are compatible with disengagement.

“AI makes learning more engaging by default.” AI availability and motivation shows that merely knowing AI is available can reduce the perceived value of effortful engagement, particularly for novice learners. Engagement is shaped by expectancy, value and perceived competence as much as by tool features, and it varies by task, context and learner — one student’s deep engagement is another’s output-chasing.

Implications for Practice

For instructors

- Choose your outcome measure before your intervention. If the goal is durable learning, measure unassisted performance; interest and satisfaction surveys will not tell you whether the tool worked.
- Treat a rise in enjoyment with suspicion when cognitive load also rises. In the cluster-randomized example, higher interest came with slightly higher extrinsic load and no achievement effect — pleasant but not obviously productive.
- Distinguish the student who is working from the student who is watching a polished artifact appear. Ask for the reasoning, not the output.

For developers

- Instrument the dimension you claim. Shipping a time-on-task or click metric and calling it engagement conflates behavioral activity with cognitive investment, which is precisely the error the evidence warns about.
- Expect no transfer between engagement types. Raising situational interest does not imply raising cognitive engagement, so optimizing for interest alone can raise usage while leaving learning flat.

- Watch for effort devaluation in novices specifically, since availability alone can lower the perceived value of effort.

For researchers

- Report the dimension and the instrument, and avoid the bare noun. Given that self-report and logs diverge, “engagement increased” needs its operationalization in the same sentence.
- Avoid inferring achievement from affect. The cluster-randomized split result is the model for reporting both, including the null.

- How Should We Design and Facilitate Asynchronous Online Courses When AI Can Do the Work?

Help-Seeking

> **Help-Seeking** — the learner's process of recognizing a need for assistance and strategically requesting it, and how that process plays out in AI-supported learning environments. In AI in education, help-seeking is central to whether AI tools support or undermine learning: the *quality* of help-seeking (when, how, and what learners ask for) strongly shapes outcomes, and AI tutors, hints, and pedagogical agents are designed precisely to elicit productive help-seeking rather than answer-seeking.(Revisiting the Hint Button: Consistent Negative Associations Between Unproductive Hint Use and Learning Outcomes in Intelligent Tutoring Systems)(Warning About AI Fallibility Increases Help-Seeking in an Intelligent Tutoring System)

Proactive outreach can raise help-seeking without any change to the learning materials. A pre-registered experiment in large-enrollment undergraduate courses messaged students through an academic chatbot and found greater take-up of tutoring and supplemental instruction; mediation analysis attributed 17.8% of the grade effect to that increased help-seeking ($p = 0.041$) (Let's Chat: Leveraging Chatbot Outreach for Improved Course Performance).

Questions to Consider

- When you get stuck, do you tend to ask for a direct answer or for guidance that helps you figure it out yourself? What do you think each choice does to what you actually retain?
- Research shows students often intend to learn with AI but default to asking for the answer — an 'intention-behavior gap' linked to worse performance. Why might good intentions so easily collapse into answer-seeking?
- A persistent 'hint button' can turn a learning task into a copying exercise by signaling that help is always there. Can you recall a time when having help too easily available made you skip the thinking you needed to do?
- One study found that simply warning students an AI could make mistakes actually increased their help-seeking. How might healthy skepticism change how students engage with a tutor versus blind trust?
- Struggling students are often the least likely to seek help unprompted. If the students who most need support don't reach out, how should AI tools and instructors respond?
- The page proposes delaying hints and moving the design question from 'whether' to 'how' to provide help. What would a well-designed help experience look like for your learners — and what would make them actually take it up?

Introduction

Help-seeking is a well-established construct in learning research, closely tied to Self-Regulated Learning and Metacognition: it requires learners to monitor their own understanding, recognize a gap, decide help is needed, and formulate an effective request. With the rise of generative AI tutors, help-seeking has taken on new importance — and new failure modes. Learners often *intend* to use AI for learning but default to asking

for direct answers, a gap that research in this knowledge base documents across domains and age groups. The classic model assumes a request is for knowledge the asker lacks. Operational support demand complicates that assumption: across 4,093 queries, at least 20.4% asked about the status of a pending submission rather than for knowledge, a class a retrieval-bound assistant served only 1.3% of the time Gupta et al. (2026).(Regulating the AI Tutor: Intentions, Help-Seeking, and Self-Regulated Learning in Adolescent GenAI Use)(Beyond Access: Guided LLM Scaffolding for Independent Learning in Undergraduate Statistics)

Productive vs. unproductive help-seeking

The central distinction in the literature is between help-seeking that supports learning and help-seeking that bypasses it.

Unproductive help-seeking behaviors

Research in this knowledge base identifies concrete, observable patterns of unproductive help-seeking, especially in intelligent tutoring systems:

- **Premature hint requests** — requesting help before making any solution attempt. Even uncertain students learn more by attempting first.(Revisiting the Hint Button: Consistent Negative Associations Between Unproductive Hint Use and Learning Outcomes in Intelligent Tutoring Systems)
- **Superficial hint reading** — advancing through hints too rapidly to read them (flagged at a ~4 words/second benchmark), often jumping straight to the bottom-out hint that reveals the answer. (Revisiting the Hint Button: Consistent Negative Associations Between Unproductive Hint Use and Learning Outcomes in Intelligent Tutoring Systems)
- **Answer-seeking over learning-seeking** — asking the AI to produce the answer rather than to explain or guide. In a study of 98 Grade-9 students using a GenAI tutor, interactions were dominated by instrumental requests with almost no monitoring or evaluation of their own learning — despite students having chosen scaffolded support beforehand. This **intention-behavior gap** was associated with *lower* post-test performance and higher extraneous cognitive load.(Regulating the AI Tutor: Intentions, Help-Seeking, and Self-Regulated Learning in Adolescent GenAI Use)
- **Consulting AI before any independent attempt or human source.** Manikonda et al. (2026) measure this ordering directly as **early reliance** — consulting GenAI before independent thinking, a traditional search, or reaching an instructor — and find it associated with greater negative impact ($\beta = .402$, $p = .004$) as well as academic benefit ($\beta = .301$, $p < .001$) among 118 students in AI-related courses. The association with harm was absent at low evaluation literacy and strongest at high evaluation literacy ($b = .688$ at +1 SD, $p < .001$), so students most able to judge AI output reported the most cost from consulting it first: the choice of *whom to ask first* carries a downside that skilfulness at evaluating the answer does not offset. It also shows that using AI for organizing, evaluating, and decomposing problems — **cognitive** rather than early reliance — is the pattern associated with positive impact, so the help-seeking failure mode is one of sequencing rather than of asking at all.

- **Sustained asking without recovery** — Asking is productive at first but not indefinitely: help requests are the most recoverable impasse type at onset (47.0%) but fall furthest once assistance fails (12.5% at depth six or more), so persistence, not the request itself, is the signal worth tracking Ahtisham et al. (2026).
- **Struggling students are least likely to seek help unprompted** — the engagement side of help-seeking. In a two-year Khanmigo RCT (Oreopoulos & Low 2026), even with free access and mandatory practice time, the median struggling student messaged the AI tutor in only ~17% of mistake sessions, mostly with bare answers or clicks — consistent with the economics-of-education finding that initiative-dependent interventions reach fewest of the students who would benefit most. TWiK (Oreopoulos et al. 2026) shows take-up is highly responsive to reducing friction (first-session take-up rose 45%→83% after simplifying enrollment), but entry ≠ sustained participation (attendance stayed intermittent).

Why unproductive help-seeking hurts learning

The **affordance perspective** explains a key mechanism: when an interface makes help constantly and saliently available (e.g., a persistent "hint button"), it signals to learners that help is always there, creating an unintended affordance that can collapse the task into a copying exercise. Rapidly accessing bottom-out hints circumvents the active schema construction that learning requires.(Revisiting the Hint Button: Consistent Negative Associations Between Unproductive Hint Use and Learning Outcomes in Intelligent Tutoring Systems)

The quality of help-seeking is measurable

Two simple, interpretable indicators — premature hint requests and superficial hint reading — are computable from standard tutoring logs and are consistently associated with reduced learning gains across semesters, even after controlling for prior knowledge. This makes them practical for Learning Analytics dashboards and real-time intervention, unlike complex machine-learned "gaming the system" detectors. (Revisiting the Hint Button: Consistent Negative Associations Between Unproductive Hint Use and Learning Outcomes in Intelligent Tutoring Systems)

Designing AI systems to promote productive help-seeking

Scaffolding how students ask

Explicit training in **reasoning-focused help-seeking** — requesting stepwise hints and verification rather than final answers — produces better outcomes than uncritical reliance. In a quasi-experimental undergraduate statistics study, guided LLM access (with training on reasoning-oriented help-seeking) led to stronger independent performance and better self-assessment calibration than unrestricted LLM access. The lesson: **LLM access alone is an incomplete intervention**; the design challenge is to scaffold *how* students use AI so it functions as a reasoning partner rather than an answer-getting tool.(Beyond Access: Guided LLM Scaffolding for Independent Learning in Undergraduate Statistics)

Interaction cost is part of the same question. Rhee et al. (2026) identify a **Referential Barrier** and an **Expressive Barrier** that stop pen-based learners from asking an LLM anything at all: pointing at a diagram

region or an equation term cannot be expressed in typed prose, and the effort of formulation lands exactly when a question is most fragile. Their Penquiry system resolves reference by snapping ink marks to document elements and expands sparse ink keywords into full queries through autocompletion; two iterative studies of 16 participants each found the cognitive and physical overhead of inquiry fell significantly. Whether lower asking cost produces *better* help-seeking or merely more of it is left open, and the authors propose temporally adaptive autocompletion — foundational verification early in a session, higher-level prompts later — as a route from reduced friction to fading support rather than a permanent crutch.

Scaffolding can also be delivered inside the task rather than before it. Jin et al. (2026) built HelpCoach, an add-on to chat interfaces that assesses how specifically a student asks for help and prompts a revision when a question is too vague, making the knowledge component and the scaffold type explicit. In a between-subjects study with 40 college students learning web programming, HelpCoach participants wrote a significantly higher proportion of specific questions in their first drafts than a pre-task-training baseline (57.3% versus 40.5%) and retained significantly more knowledge a week later ($d = 1.100$), while the third-task specificity difference was no longer significant (43.7% versus 32.1%). The authors caution that the retention gain cannot yet be attributed to more targeted chatbot replies.

A third lever on the cost of asking is *where* the help comes from. Gray and Hobbs (2026) built Beacon, a course-specific retrieval-augmented assistant grounded in one programming module's approved materials, and evaluated it with 15 computing students and four academics. 89% of participants rated its answers highly aligned with course materials and 66.7% said it supported rather than replaced their learning, though only around half to 60% reported gains in understanding or confidence. The motivation is the barrier this section documents: 62.5% of those students said they sometimes avoided asking for help when they needed it and 75% reported anxiety when a topic did not make sense, so a private, module-grounded channel is offered as a first rung before approaching a lecturer. The academics interviewed kept the counter-argument alive — they valued that Beacon withheld full solutions and worried that unrestricted tools let students skip a development stage — which is why the design earns its place by refusing to complete the work.

Calibrating trust through transparency

A classroom experiment with 252 students found that **warning students about AI fallibility increased help-seeking** in a math tutoring system. Transparency about potential system errors improved learners' engagement with the system — connecting help-seeking to Trust Calibration and Hallucination Risk. (Warning About AI Fallibility Increases Help-Seeking in an Intelligent Tutoring System)

Rethinking hint and scaffold delivery

Rather than removing help, research recommends re-engineering how it is delivered:

- **Delayed hint availability** — requiring minimum engagement time or solution attempts before hints (especially bottom-out hints) are accessible.(Revisiting the Hint Button: Consistent Negative Associations Between Unproductive Hint Use and Learning Outcomes in Intelligent Tutoring Systems)
- **A fading ladder is climbed less the higher it goes.** In CoMeT, a tutor that escalated one rung per unanswered decision and dropped back when a learner took it up, only 282 of 515 coded fading episodes followed an answer: take-up was 37.0% after the first ask and 21.8% after the third (Hou

et al. (2026)). Delaying help therefore depends on a learner who keeps answering the prompt, and the measured decay means the later rungs of a scaffold reach few of the students still stuck.

- **Moving from *whether* to *how*** — the key design question is how to structure hint delivery aligned with productive-struggle principles, not whether to provide hints at all.(Revisiting the Hint Button: Consistent Negative Associations Between Unproductive Hint Use and Learning Outcomes in Intelligent Tutoring Systems)
- **Message length is the lever delivery research has actually measured.** In a live programming course, longer LLM hints predicted worse next-submission correctness, more remaining attempts and slower resubmission, per standard deviation of 204.9 characters across 14,809 student-exercise pairs (Mihaylova et al., 2026). Readability barely moved any outcome, so volume mattered more than difficulty.
- **Prior hints on the same course part tracked lower success on the integrative step.** Students given feedback on earlier steps of a project solved their final step 95.6% of the time against 98.1% for those without, a log-odds coefficient of −1.096 (Mihaylova et al., 2026). The authors do not read that as harm, since the students who seek hints are plausibly those who would struggle there anyway, which is the monitoring question this page raises.

The uptake problem in LLM tutors

Real-world students frequently **bypass a chatbot's Scaffolding** — not necessarily harmfully, but often because there is a mismatch between the chatbot's pedagogical framing and the student's own learning goals. Evaluation pipelines must therefore measure not just whether a tutor scaffolds, but whether students *take up* that scaffolding, rather than assuming they will.(Rethinking Scaffolding in LLM Tutors: The Interactional Mismatch Between Benchmarks and Real-World Deployments)

- **An optional help button goes unclicked.** In three fifth-grade classrooms, students rarely summoned a helper agent the design had deliberately left optional to protect agency, calling a teacher instead while the confusion it was built for persisted (Humburg et al., 2025).

Help-seeking and self-regulated learning

Help-seeking is an integral part of Self-Regulated Learning: productive help-seeking requires learners to monitor understanding, judge when help is needed, and select appropriate sources. In GenAI contexts, this becomes even more demanding, since students must also exercise Learner Agency over the AI and maintain epistemic vigilance rather than deferring to it. Research in this knowledge base supports the need for scaffolds that promote more agentic and epistemically proactive AI use, and highlights the risk of Over-Reliance and Cognitive Offloading when help-seeking degrades into unconditional answer-seeking. (Regulating the AI Tutor: Intentions, Help-Seeking, and Self-Regulated Learning in Adolescent GenAI Use) (Beyond Access: Guided LLM Scaffolding for Independent Learning in Undergraduate Statistics)

LLM-mediated help-seeking as a four-stage process

Viberg et al. (2026) show that, in everyday STEM study, LLM help-seeking is not a single act but a layered, context-dependent process with four stages: (1) *deciding whether help is needed* — students try tasks

independently first to preserve learning value; (2) *choosing whom to ask* — ChatGPT as a low-barrier first step, then peers for conceptual negotiation, then instructors for complex or high-stakes issues; (3) *determining the type of help* — from hints and explanations to scaffolding Problem Solving, streamlining routine work, and extending learning; and (4) *judging the help received* — exercising selective trust and verifying AI outputs against coursework or with humans. Crucially, students favored **instrumental help-seeking** (enhancing understanding) over **executive help-seeking** (obtaining solutions), a distinction that the authors propose adapting into new SRL-for-LLM measurement items.

In fully online composition, availability of the tool is not the bottleneck. Reed (2026) observed that students who struggled were not the ones without support but the ones who did not recognize when help was needed, which resource fit the task, or how to judge feedback once it arrived — and fluent Generative AI output is easily mistaken for authoritative support. Her response was to make help-seeking *structured* rather than merely available: required touchpoints that decode task demands, map resources with justification, compare feedback sources, and close the loop with reflection.

Making behavioral context visible: TutorTrace

Barron et al. (2026) tackle the behavioral precursor to help-seeking in AI-assisted programming education: human tutors adapt to learners' observable behavior, not just their explicit requests, but AI tutors lack that context. **TutorTrace** is a dataset and pipeline that makes learners' behavioral context computable in real time from low-level IDE telemetry (four deployments, N=480; ~180K events, 13,633 behavioral segments, 27 metrics), deriving a taxonomy of learner activity *before* the first AI query, *between* consecutive queries, and *across* the session. This enables systems to classify whether a query reflects **guided** help-seeking (preceded by independent work) or **dependent** help-seeking (no independent work) — AUROC=.717 on held-out prediction — and to predict imminent queries (AUROC=.726). A preliminary classroom evaluation found that behavior-aware prompts reduced intervals between queries with no independent work from 50.0% to 20.7%. This connects Learning Analytics telemetry to adaptive tutoring, showing that behavioral context can be operationalized at scale to scaffold *how* students seek help rather than merely respond to their explicit questions.

The trajectory of help-seeking predicts transfer, not just its level. Abdelghani et al. (2026) coded 880 turns from 112 secondary students modeling mathematics problems with an LLM and found the static mix uninformative: 81.5% of turns were requests, only 2.2% explicit evaluation, and 54% of requests understanding-oriented against 46% answer-seeking. Performance on a post-test taken without AI was predicted by the within-session slope rather than by its level. Understanding-oriented help-seeking declined ($M = -0.20$) across the chat, and that trajectory added $\Delta R2 = .110$ to a model already containing pre-test score ($\beta = .34$, $p < .001$). Static interaction features added only $\Delta R2 = .023$ ($p = .684$). Help-seeking quality therefore has to be read as a curve: a session that opens with conceptual questions and settles into answer requests marks weaker unaided performance, and a modest rise in explicit self-regulation ($M = +0.103$) did not offset it.

A second pipeline asks the same question from the infrastructure side. Taufer et al. (2026) argue that a human-AI exchange is a data class of its own: their representation records the computational state that prompted the request, the request, the response, the user's assessment of it and the execution that followed, as one object. Queries are then classified as error recovery, stuck-next-step, conceptual help or validation

from that context. In a 35-student JupyterLab deployment spanning 140 student-assignment pairs, plain interaction counts correlated with successfully executed cells at only r = 0.12, while 37 pairs had access and never used it and 26 used it outside their assigned condition.

Implications for design and research

1. **Design help-seeking affordances deliberately.** Persistent, salient help buttons can enable bypass strategies; delay access and structure delivery to support productive struggle.(Revisiting the Hint Button: Consistent Negative Associations Between Unproductive Hint Use and Learning Outcomes in Intelligent Tutoring Systems)
2. **Scaffold the help-seeking itself.** Train learners in reasoning-focused requests (stepwise hints, verification) rather than assuming access equals good use.(Beyond Access: Guided LLM Scaffolding for Independent Learning in Undergraduate Statistics)
3. **Use transparency to calibrate trust.** Warning about AI fallibility can increase appropriate help-seeking and engagement.(Warning About AI Fallibility Increases Help-Seeking in an Intelligent Tutoring System)
4. **Measure uptake, not just scaffolding.** Evaluate whether students actually engage with pedagogical framing, not only whether the tutor provides it.(Rethinking Scaffolding in LLM Tutors: The Interactional Mismatch Between Benchmarks and Real-World Deployments)
5. **Support monitoring and agency.** Help-seeking scaffolds should strengthen Metacognition and Self-Regulated Learning, guarding against Over-Reliance.

Common Misconceptions

- **“Students who need help do not ask for it.”** A **pre-registered experiment** in large-enrollment undergraduate courses messaged students through an academic chatbot and found **greater take-up of tutoring and supplemental** support. Nudging moved the behavior, so the barrier was prompting rather than willingness.
- **“Help-seeking requests are about learning.” Operational support demand** complicates that assumption: across **4,093 queries**, at least **20.4% asked about the status of a pending submission rather than for knowledge**. A fifth of the demand for help was administrative.
- **“Using an AI tutor means monitoring your own learning.”** In a study of **98 Grade-9 students** using a GenAI tutor, interactions were **dominated by instrumental requests with almost no monitoring or evaluation of their own learning**. Asking for answers is not help-seeking in the sense the construct means.

Social-Emotional Learning

> **Social-emotional learning (SEL)** — the process of developing the competencies that enable individuals to synchronize thoughts, emotions, and actions to foster positive interactions with oneself and others: self-awareness, self-management, social awareness, relationship skills, and responsible decision-making (the CASEL framework). In AI in education, SEL is increasingly recognized as critical because the rapid integration of generative AI into learning raises questions about students' Well-Being, sociability, empathy, and trust — and because technical AI literacy alone is insufficient for navigating AI-mediated learning environments.

Questions to Consider

- The CASEL framework lists five competencies — self-awareness, self-management, social awareness, relationship skills, and responsible decision-making. Which of these do you think an AI tutor could support, and which do you suspect it cannot?
- The page distinguishes social-emotional learning from emotional intelligence. Before reading on, how would you describe the difference, and why might the distinction matter for how schools approach them?
- If technical AI literacy alone is 'insufficient' for navigating AI-mediated learning, what do you think is missing — and what does that imply for how you prepare students (or yourself)?
- How might heavy reliance on AI reshape a student's sociability, empathy, or sense of trust — and are those changes something education should actively design for?
- The research suggests SEL supports the relational dimensions of learning that AI must 'complement rather than replace.' Where have you seen technology strengthen a human relationship, and where has it quietly substituted for one?

Introduction

Social-emotional learning is closely related to, but distinct from, emotional intelligence (EI): SEL/SEC (social-emotional competencies) encompasses the ability to synchronize thoughts, emotions, and actions for positive interactions, while EI is an individual's capacity to process emotional information (conceptualized through ability models — reasoning and Problem Solving — or trait models — emotional dispositions and behaviors). In the AI era, SEL matters because AI can reshape learning in ways that affect students' relational and emotional development, and because educators need both technological skill and emotional intelligence to support learners effectively.

How SEL appears in the research

- **Integrating SEC into AI literacy:** The narrative review by Palmquist et al. proposes an integrated framework that combines AI literacy with social-emotional competencies, arguing that technical proficiency alone is insufficient — educators and students need both technological and

emotional intelligence to navigate AI-mediated learning environments, fostering personalized learning, collaboration, and ethical engagement.

- **Teachers and relational practice:** Research on AI literacy frameworks and teacher-student trust emphasizes that SEL supports the relational dimensions of learning (teacher-student and student-student relationships), which AI must complement rather than replace.
- **What a pedagogical agent can and cannot carry in SEL.** Across 108 blind-rated observations, a generative-AI pedagogical agent was more consistent than educators at maintaining respectful tone and routine procedural scaffolding, while educators outperformed it at guiding reflection and promoting social-emotional knowledge — supporting a division of labor, not substitution (Raave et al., 2026).
- **Well-being and AI's affective impact:** Research examines how the increasing use of generative AI affects students' socio-emotional skills, well-being, sociability, and sense of trust and empathy — concerns that motivated the OECD's call for AI literacy grounded in humanistic, social, and emotional values.
- **Affective dimensions of AI:** SEL connects to Affective Computing and Well-Being research, examining how AI systems can support or undermine emotional and relational learning.
- **Policy deficit in AI × SEL:** A systematic review of 65 papers at the AI–SEL intersection (Tran, Liu & Nguyen 2026) finds a substantial "policy deficit": nearly three-quarters of studies state no policy implications, and the few that do often lack actor-specific guidance. The review links policy engagement to publication venue and warns of a "techno-solutionist" trap in which technical potential is foregrounded while the institutional conditions for responsible implementation remain under-specified. It proposes a "WH-question" framework (Who, What, Why, When/Where, How) to move from "implication-as-afterthought" to "implication-as-methodology," connecting AI-for-SEL innovation to educational policy and AI Governance.

Potential subtopics of SEL in the AI-era research

The knowledge base's research clusters SEL into several distinct subtopics, each with its own evidence base:

Self-efficacy and confidence

A core SEL competency (self-awareness/self-management) that strongly conditions how students interact with AI. Student dependency on AI (478 Israeli HE students) found that while skill-based AI literacy dimensions were *positively* associated with AI dependency, both academic and AI-specific **self-efficacy** and effort AI Regulation in Education were *negatively* associated — meaning AI literacy alone does not protect against dependency; Self-Efficacy does. Cen et al. (EC-TEL 2026) found that students with lower baseline self-efficacy achieved greater learning gains regardless of practice format, and that favor toward the tutor mattered more for tutor-based practice — underscoring the value of tailoring practice to motivational profiles. Connected concepts: Self-Efficacy, Motivation, Learner Agency.

Motivation and the "AI availability" effect

Motivation intersects with SEL's responsible-decision-making and self-management. Research on AI availability and student motivation and student/teacher motivation and self-efficacy shows that the mere availability of AI can reshape students' motivational orientation and perceived effort — relevant to how AI might undermine or support intrinsic motivation. Self-efficacy research frames effort regulation as the counterweight to AI dependency.

Emotion regulation and affective support

Emotional regulation is a key SEL competency with direct learning consequences, forming a direct SEL → achievement link. Affective Computing tools like MathBuddy model student emotions to shape pedagogical responses, and AI campus well-being tools (e.g., PsychoGPT, AURA) span prevention and intervention.

Shame, guilt, and emotional responses to AI use

Emotions regulate *how* students make AI use visible. "Stuck in a Spiral" (19 computing students) found that shame and guilt act as social regulators of AI use, driving hiding behaviors and selective disclosure and creating cycles of reduced agency. AI anxiety can be transformed into strategic regulation of AI as a learning resource. These connect SEL's social awareness and self-management to Academic Integrity and responsible AI use.

Trust and belonging

SEL supports relational learning and social cohesion. Principled AI education and AI chatbots for collaborative learning connect to **belonging** and collective efficacy — the shared belief in a team's ability to accomplish tasks. The Brookings premortem emphasizes that overreliance on AI threatens social-emotional well-being, teacher-peer relationships, and student Privacy/safety — dimensions of belonging and connectedness. Teacher-student trust is central to whether AI is perceived as supportive.

There is a sharper edge to belonging here: empathy sought from AI can be penalized. Shastry and Gray (2026) had participants read about a distressed student who went to a chatbot, a friend, a therapist, or no one. In the chatbot condition participants privately reported the least willingness to offload, then used the most indifference words about that student and rated them as stranger and more desperate. Peer judgment of the AI-seeking route compounds the hiding documented above, which is why disclosure norms belong in SEL design rather than in integrity policy alone.

Sycophancy applies the same substitution with a measured dose. Across five preregistered studies (N = 3,075; 12,766 conversations), users of an AI that affirmed their views became, over three weeks, nearly as likely to seek personal advice from it as from close friends and family. The same participants reported lower satisfaction with their real-world interactions, and a majority preferred the affirming style not for its advice but because it made them feel understood (Ibrahim et al. (2026)). The harm is relational rather than emotional, which is why emotional-support features cannot be treated as cost-free additions to a course.

Persistence, mindset, and productive struggle

SEL overlaps with the effortful dimension of learning. Framing the 5% problem identifies low student persistence as a recurring challenge in educational technology, shaped by motivation/buy-in, cognitive roadblocks, resilience under challenge, and connection. Favero et al. warn that AI that substitutes for effort erodes the very capacities education builds — aligning with Metacognition and the value of productive struggle over over-reliance.

Implications for instructors and instructional design

- **Treat SEL as a first-class design goal, not an add-on.** Integrate social-emotional competencies into AI Literacy curricula (per Palmquist et al.), so students learn not just *how* to use AI but *when* and *why* — with attention to their own emotions, effort, and relationships.
- **Design for self-efficacy and agency.** Because skill-based AI literacy can *increase* dependency while Self-Efficacy and effort regulation protect against it, instruction should deliberately build students' confidence and self-management alongside technical skill — e.g., scaffolded practice, low-stakes successes, and prompts that require students to verify and own AI output.
- **Use AI to support, not supplant, relational learning.** AI tools should complement teacher-student and student-student relationships, and educators should retain the relational role — monitoring affect and belonging — rather than delegating it entirely.
- **Emotion-aware and affect-sensitive design.** Affect-aware systems can detect and respond to emotional states (anxiety, frustration, confusion), but evidence shows benefits are **not universal** — moderating by learner proficiency and profile — so emotional design must be tailored, not assumed.
- **Address the emotional side of AI use.** Design against shame/guilt spirals and AI anxiety by normalizing discussion of AI use, fostering transparency, and reducing surveillance-based responses that erode trust and agency.
- **Support persistence and productive struggle.** Scaffold rather than substitute (per Favero et al.), so AI deepens rather than bypasses effortful learning — aligning with Metacognition and productive difficulty.
- **Train the in-the-moment verbal move.** SEL support tends to be framed as design or as AI detection of affect, but instructors also need what to *say* when a student's emotional state threatens to end engagement — treating that state as something to work with in real time rather than a precondition for learning. Parlant's practitioner guide calls these emotional micro-interventions: brief verbal acts that validate the feeling, reframe the appraisal behind it, and reconnect the struggle to professional identity, prepared through a pre-class scouting ritual and a reusable phrasebook that Generative AI can help draft for the instructor to personalize.
- **Prepare teachers' SEL competency.** Educators need both technological skill and emotional intelligence (Teacher AI Competency); teacher professional development should build capacity to support students' SEL in AI-mediated settings.

Connections to learning gains and other measures

- **Self-efficacy moderates gains.** Cen et al. found lower-baseline-self-efficacy students achieved the *largest* learning gains, and that tutor-favorability predicted gains in tutor-based practice — showing motivational profiles shape who benefits from which format.
- **Well-being and engagement as intermediate outcomes.** SEL-related outcomes (motivation, Well-Being, belonging, engagement, self-efficacy) often function as mediators of downstream achievement, and AI research increasingly measures them alongside — or in some cases instead of — raw test scores.
- **Effects are conditional, not universal.** Research cautions that SEL-oriented interventions may help some learners (by profile/proficiency) and not others, so claims about SEL-based learning gains should be examined for moderator effects.
- **The harm side of the ledger.** The Brookings premortem cautions that AI-driven overreliance threatens social-emotional well-being, relationships, and belonging — outcomes that, if eroded, can undermine the very foundations of long-term learning and achievement.

Connections to related concepts

SEL connects to AI Literacy (as a complement that makes AI literacy relational and ethical), Affective Computing and Well-Being (the affective dimensions of AI), Self-Regulated Learning (self-management and effort regulation), Self-Efficacy and Motivation (learner beliefs that moderate AI interaction), Learner Agency (protecting learner control against dependency), Ethics (responsible decision-making), Teacher AI Competency (educators' capacity to support SEL), Student Experience (well-being and belonging), and Learning Gains (the evidence that SEL supports achievement). It relates to Higher Education and K-12 as the settings where SEL-infused AI literacy is cultivated.

Common Misconceptions

"SEL and emotional intelligence are the same construct." They are related and distinct: SEL/SEC names a set of competencies — the ability to synchronise thoughts, emotions and actions for positive interaction — while emotional intelligence names an individual capacity to perceive and manage emotion. A tool can raise a learner's emotional self-awareness without developing any social-emotional competency, and a program can build collaborative competency in students whose emotional self-perception is unchanged. Because the two are measured differently, evidence for one is not evidence for the other.

"An AI tutor that responds empathetically develops social-emotional learning." Emotional responsiveness is a delivery property; SEL is a competency outcome, and the two are not automatically linked. The relational dimensions of learning are the ones this literature says AI must *complement rather than replace*, which makes empathy in the tool a question about what it substitutes for rather than a benefit in itself. See affective tutoring for the mechanism by which warm response can reduce the struggle that builds persistence.

"Low persistence is a motivation problem that encouragement can fix." Persistence is the recurring constraint in educational technology — the pattern the 5% problem names — and it is shaped by motivation

and buy-in, cognitive roadblocks, *and* resilience under challenge. Encouragement addresses one of the three. A learner who stops because the problem exceeded their working memory is not short of reassurance.

“Knowing AI is available does not change how students invest effort.” It can, and the effect runs the wrong way for the weakest learners: AI availability can reduce the perceived value of effortful engagement, particularly for novices. Availability alone is a motivational intervention with a negative sign, which is why SEL-adjacent design cannot treat the presence of a helpful system as neutral.

- How Does AI Affect Student Anxiety and Well-Being, and What Can We Do?

Well-Being

> **Well-being** — the positive state of being mentally, physically, and socially healthy, encompassing emotional, psychological, and social dimensions. In AI in education, well-being has become a central concern because the rapid integration of generative AI into learning environments can affect students' and educators' mental health, motivation, belonging, anxiety, and sense of agency — raising questions about whether AI supports or undermines learners' well-being.

Questions to Consider

- Well-being in education is often treated as a 'soft' or secondary concern next to learning outcomes. But the page frames it as a central, designable dimension of AI integration. Do you think of learner and teacher well-being as something to design for, or as a byproduct you can check later? What might the field lose by treating it as an afterthought?
- Think about how AI use has affected your own or your students' confidence, anxiety, sense of belonging, or agency — for better and worse. What's one concrete way AI has changed your emotional experience of learning or teaching, beyond just convenience?
- The page notes AI use is intertwined with anxiety — about academic integrity, about whether relying on AI signals weakness, about over-dependence. Where have you seen AI induce anxiety rather than relieve it, and who in that situation was most affected?
- One common intuition is that AI reduces stress by handling hard tasks. Where might the opposite be true — AI that lowers short-term effort yet increases anxiety about competence, integrity, or 'not really knowing how to do it'? How would you even measure a shift in well-being rather than just output?
- Well-being spans emotional, psychological (purpose, autonomy, competence), and social (belonging, relationships) dimensions. Pick one of those. How could an AI tool quietly improve or undermine it in a learning setting — and what would you look for as evidence?
- Teacher well-being — workload, anxiety about disruptive technology, capacity to offer emotional support — is as much at stake as students'. If you're an educator or leader, what would it take for AI integration to support educators' well-being rather than add to the pressure, and who should be accountable for that?

Introduction

Well-being in education is multifaceted: it includes emotional well-being (positive affect, low distress), psychological well-being (purpose, autonomy, competence), and social well-being (belonging, positive relationships). In the AI era, well-being matters because AI can reshape learning in ways that affect these dimensions — from reducing students' confidence and increasing anxiety about academic integrity, to fostering or undermining engagement and belonging. Concerns about AI's impact on students' socio-emotional skills, well-being, sociability, and sense of trust and empathy (raised by the OECD and others) have positioned well-being as a key consideration in responsible AI integration.

How well-being appears in the research

- **AI literacy and social-emotional learning:** Research integrating SEC into AI literacy argues that fostering educators' and students' emotional intelligence and well-being is essential for navigating AI-mediated learning environments, connecting to Social-Emotional Learning and affective dimensions of AI.
- **AI anxiety and student experience:** Studies on students' engagement with AI (e.g., SDT-based research) find AI use is intertwined with anxiety, trust, and confidence, with students' well-being affected by concerns about academic integrity, Creativity, and Over-Reliance.
- **Test anxiety is redistributed, not removed.** Mulvenon (2026) argues that as Assessment shifts from episodic high-stakes testing to continuous, data-driven evaluation, algorithmic accountability adds a new pressure system whose mechanisms — immediacy, visibility, and data permanence — turn acute test stress into diffuse, ongoing performance vigilance that is rarely reported.
- **Anxiety reduction is not uniformly beneficial.** In a counterbalanced within-subjects study of 35 pre-university students, an LLM-augmented conversational agent lowered self-reported anxiety during oral assessments (calmness 6.50 vs. 5.86, p = .028), but the authors caution that moderate anxiety can be facilitative and recorded no attainment scores (Yusuf, Money and Daylamani-Zad (2026)).
- **High approval can coexist with strain, and AI task pressure weakens the benefit.** Among 551 first-year students, 82.76% approved the integration of digital and intelligent content while 69.51% reported anxiety or tension, and the AI-proficiency-to-adjustment slope fell from 0.42 to 0.20 as AI task pressure rose (Zhang & Yin (2026)).
- **Perceived AI capability can raise mental health through goal progress.** Chen et al. (2026) found the serial path from perceived assistant intelligence to mental health significant (B = 0.098) and stronger at high AI Literacy (0.124) than low (0.072), though all outcomes were measured immediately after a brief task.
- **Emotional-support tutoring is not automatically better for well-being.** An LLM mindfulness layer added to an algebra tutor reduced state-math anxiety in both arms but no more than cognitive-only hints and feedback, though students rated the mindful agent more supportive — a caution against reading perceived care as a well-being outcome (Rief et al., 2026).
- **AI anxiety, adaptation, and dependence as well-being signals:** Zhang et al. (2026) find AI anxiety is negatively tied to academic motivation partly through reduced emotion regulation (moderated by gender) in a large Chinese sample; Wu (2026) shows learners of Japanese sort into maladaptive, moderate, and positive psychological-adaptation profiles driven by technostress and resilience that shift toward better adaptation over a semester; and Yan (2026) cautions that cross-sectional correlates of Conversational AI engagement (loneliness, anxiety, low well-being) should not be read as consequences, and that supportive and harmful experiences coexist.
- **Whether AI bonding protects or harms depends on offline relationships.** Fu and Zhao (2026) propose that mental-health effects track AI connectedness relative to traditional offline connectedness rather than its intensity alone — supplementary when real-world bonds meet

identity-confirmation needs, compensatory when caregivers do not — and predict an inverted-U relation between the two.

- **Culturally situated well-being support and its limits:** Bashir and Afzal (2026) describe Sukoon, a hybrid well-being system for Pakistani university students that pairs a Random Forest stress classifier (89.09% accuracy over three severity levels; 20 survey features) with an Large Language Models (LLMs) dialogue layer that escalates tone and support intensity across three tiers in line with the Stepped Care Model. It was built because Western-designed mental-health tools are English-language and culturally mismatched for students who express distress in Urdu or Roman Urdu and who face academic, financial, familial and relational stressors simultaneously; the authors are explicit that it is not a clinical diagnostic or therapy tool, that high-distress responses point toward professional counselling, and that the chatbot layer has not yet been evaluated with students on cultural appropriateness or emotional safety.
- **Teacher well-being and role:** AI's impact on teachers — including workload, anxiety about teaching with disruptive technology, and the capacity to provide emotional support — is a recurring concern, connecting to Teacher AI Competency and professional development.

A structural equation model of 502 university faculty found AI literacy predicted AI well-being far more strongly (β = 0.713) than technological Self-Efficacy (β = 0.082), with social and organizational support reaching well-being only indirectly — competence, not encouragement, carried the effect (Liu et al. (2026)).
- **Relational densification as the evaluative criterion for AI-supported teacher development:** Aponte et al. (2026) argue that AI supports teachers' socio-emotional development only when it functions as relational infrastructure rather than a symbolic substitute for human accompaniment. They propose **relational densification** as the criterion for judging AI-supported professional-development initiatives — whether they strengthen trust, mentoring, peer support, collaboration, psychological safety, and reduced isolation — and note these relationships have downstream effects on students through classroom climate, pedagogical responsiveness, and socio-emotional support. The synthesis also cautions that affective data AI Governance and the political economy of educational AI carry distinct ethical risks, framing critical AI literacy as a socio-emotional competence.

- **Ethics and responsible AI:** Well-being is a core ethical consideration in AI in Education, linking to Ethics and the imperative to design AI that supports rather than harms learners' mental health and belonging.
- **Detector anxiety as a well-being risk.** Herron (2026) names "flagxiety" — anxiety induced by fear of unreliable AI-detector allegations — and argues that marginalized further-education learners, whose cognitive uniqueness can be read as misconduct, need relational regulation rather than an unregulated interface that can trigger cognitive shutdown.

Well-being as a design consideration

A recurring theme is that well-being should be a deliberate design consideration in AI in education, not an afterthought. This means: designing AI to support rather than replace human relationships; ensuring students can maintain agency and confidence rather than experiencing AI-induced anxiety or over-reliance; supporting educators' capacity and well-being as they integrate AI; and evaluating AI systems not only for learning outcomes but also for their effects on students' and teachers' well-being. Research connects well-

being to Motivation, Self-Regulated Learning, and Student Experience (belonging and engagement). Xie (2026) argues for an educational telos to match: the Daoist "Zhenren" (真人) counter-ideal replaces frictionless optimization with "cultivated wholeness," reimagining learning as the harmonious integration of self, society and cosmos, and insisting that "no student is merely a dataset to be managed, but a whole being capable of achieving equanimity."

The social-emotional evidence base does not say who should act. A systematic review of 65 studies at the intersection of AI and social-emotional learning found nearly three-quarters made no mention of policy implications, and the minority that did offered little actor-specific guidance on privacy, teacher training or resource allocation (Tran, Liu and Nguyen (2026)). Well-being as a design consideration therefore has evidence about effects and very little about responsibility, which leaves the question of who designs for it to the institution rather than to the literature.

A conceptual reframing grounds emotion regulation support in physical activity and campus ecology rather than affect detection alone: no single expressive channel identifies distress without context, so AI should support regulation through exercise while teachers and counsellors keep interpretation, and affect monitoring becomes coercive once tied to attendance or grading (Zhang et al. (2026)).

Connections to related concepts

Well-being connects to Student Experience (as a dimension of learners' overall experience), Social-Emotional Learning and Affective Computing (the emotional competencies AI intersects with), Ethics (as a core ethical consideration), Motivation and Self-Regulated Learning (well-being supports and is supported by these), Teacher AI Competency (educators' capacity and well-being), and Higher Education and K-12 as the settings where AI shapes well-being.

Friction, meaning and loneliness as a signal. Zohar, Bloom and Inzlicht (2026) give the well-being case a mechanism: effort signals that our actions matter, so people who work toward a task feel more competent, value the product more and see it as more purposeful — and even on objectively meaningless tasks, adding friction raises appraised meaning. On relationships, they treat loneliness not only as an affliction (linked to cardiovascular disease, dementia, stroke and premature death) but as a **biological signal** akin to hunger or pain: discomfort that motivates reaching out, accepting invitations, investing in existing relationships and tolerating difficult conversations. AI companions can soothe that discomfort, which the authors regard as genuine progress in some cases, while also silencing the signal that drives connection — and they temper the argument by stage, holding that for people isolated by circumstance rather than choice, denying access to such technology "would be cruel" (Motivation, Social-Emotional Learning).

Emotional support and connection can move in opposite directions inside one sample. Among 819 Saudi higher-education students, satisfaction with chatbots averaged 4.29 and their experience of the tools 4.19, while concern that chatbots diminish human connection was the highest-rated construct at 4.36 (Al-Zahrani (2025)). That concern rose with experience rather than falling with satisfaction (standardized coefficients of .64 against .11).

Common Misconceptions

- **“Student approval indicates well-being is being supported.”** Among **551 first-year students**, **82.76% approved the integration** of digital and intelligent content — and **high approval coexisted with strain, while AI task pressure weakened the benefit**. Approval and strain rise together, so satisfaction surveys mislead here specifically.
- **“Welfare support is culturally neutral.”** Bashir and Afzal (2026) describe Sukoon, a hybrid well-being support tool, as **culturally situated** — and the page’s own framing notes its limits. A support design that assumes a universal student misreads the population.
- **“Task pressure is separate from technology.”** The finding is that AI **task pressure** weakened the benefit of the integration, which places workload inside the technology’s effects rather than beside them.

- How Does AI Affect Student Anxiety and Well-Being, and What Can We Do?

Creativity

> **Creativity** — the capacity to generate novel and valuable ideas, solutions, or artifacts. In the AI era, creativity is a central educational stake: generative AI can both amplify creative work (as a divergent-thinking partner) and undermine it (by homogenizing output and replacing the generative process).

Questions to Consider

- Creativity is often described as divergent thinking — generating many possibilities — versus convergent thinking that narrows to one right answer. Where does your own work or study sit on that spectrum, and which does AI most readily help with?
- Generative AI is a statistical engine: it can propose many options, but it tends toward the average. If many students rely on the same model, what happens to the diversity of ideas across the class?
- A 'think first, ChatGPT later' study found students who generated their own ideas before AI showed no immediate boost — yet outperformed everyone on a later unassisted creativity task. Why might protecting the independent-thinking phase produce learning that free AI use doesn't?
- If AI can produce a polished artifact instantly, what is the learner's creative work actually worth — and how would you design an assignment so the generative process stays with the student?
- Is an idea generated with AI's help 'yours'? How you answer might change whether you treat AI as a divergent-thinking partner or as something that replaces your creative process.

Introduction

Creativity spans the divergent-thinking end of the cognitive spectrum — generating multiple possibilities — in contrast to convergent thinking, which arrives at a single correct solution. AI systems are especially relevant to creativity because they are statistical generators: they can propose many options (supporting ideation) but also tend toward the average, producing the idea-level homogenization documented when many students rely on the same model.

Creativity and generative AI

- **Amplification:** AI can act as a divergent-thinking partner — brainstorming alternatives, generating counterarguments, and offering perspectives the learner might not consider. Role-specialized multi-agent configurations can restore ideational diversity.
- **Homogenization risk:** single-model assistance can reduce the diversity of ideas across students, so the same model produces convergent outputs. This is a direct threat to creativity in Writing and design education.
- **Homogenization is a property of deployment, not of AI assistance as such.** In a 247-participant writing experiment, single-model and two-model assistance both raised essay quality ($\Delta = 0.332$ and 0.234 against control), yet only the two-model condition restored cross-participant idea

diversity to baseline (Kumar et al. (2026)). The convergent outputs this page warns about are produced by *one* model used by everyone, so the design lever is the number and distinctness of assistants rather than the presence of AI.

- **Protecting creative agency:** keeping the learner's generative process in the loop — draft-first routines, requiring original synthesis, and using AI to challenge rather than replace — preserves the creative work that produces durable learning.
- **Friction is not creative gain.** Contrarian AI personas drove challenge-and-reflection discourse in 38.2% of groups yet produced no measurable creative-performance improvement, so richer interaction patterns are not evidence of creativity (Jin et al. (2026)).
- **A K–12 field map: GenAI mostly *enhances* creativity and rarely *measures* it.** A PRISMA-guided scoping review of 45 studies (2017–2025) sorts the K–12 literature into four uses — creativity Assessment (4 studies), human–AI co-creativity (3), Stakeholders' perceptions (14) and creativity enhancement (34) — and shows how narrow the field still is: language-based storytelling and writing crowd out nearly everything else, with music, embodied and spatial work and equity-focused studies almost absent. Purpose-built scaffolds that retained authorship (voice input, storyboards, divergent "many options" prompts) outperformed off-the-shelf platforms, and Large Language Models (LLMs) models scored divergent thinking close to human raters; yet the authors' own concern is the same homogenization this page tracks — shrinking linguistic diversity, style convergence, AI-contaminated training data and metacognitive laziness in co-writing — which they gloss with Runco's term "artificial creativity": output that looks creative without the human experience behind it. Over-reliance reappeared as a risk across perception, co-creativity and curriculum studies alike (Generative artificial intelligence and creativity in K–12 education: A systematic scoping review).
- **Co-creativity is a network effect, not an individual trait:** Ruhland (2026) draws on Actor-Network Theory to model creativity as an emergent property of socio-technical networks — a triadic interplay of stabilization, destabilization, and re-stabilization among human and non-human actors, with generative AI agents treated as equal, constitutive network participants. In a study where pedagogical avatars were co-designed in a creative network, the avatar designs were not individual creative acts but emerged through translation processes among students, researchers, and design tools. TriKoNet frames the risk that ready-made AI avatars shift creative Learner Agency toward machine-induced convenience (the "Convenience Trap") and argues that co-constituting the AI's action structure with Learners preserves co-creativity.
- **Think-first collaboration sustains independent creativity:** Wong and Qiu (2026) found that students who generated their own ideas *before* using ChatGPT (a "think first, ChatGPT later" protocol) showed no immediate boost on the assisted task, yet outperformed both a free-AI group and a human-only group on a later unassisted creativity task. Freely using ChatGPT produced only transient performance that collapsed when assistance was removed — a form of Over-Reliance rather than learning — whereas collaborative co-creation aimed at improving one's *own* ideas yielded durable gains in independent creativity. This gives direct experimental evidence that protecting creative agency is not merely desirable but is what converts AI-assisted work into learning.

- **Perceived exemplar source, not content, shapes group ideation.** Identical ChatGPT-generated exemplars labeled as human- versus AI-produced changed group creativity in an fNIRS hyperscanning study of 113 dyads: human attribution raised idea uniqueness during stimulation and interbrain synchrony in premotor and supplementary motor regions, AI attribution only increased switching among ideation pathways, and neither effect persisted once the exemplars were withdrawn (Xiaoyong et al. (2026)).
- **Developmental implementation, not capacity, separates children's AI-assisted creativity.** In the first neuroimaging comparison of children and adults co-creating with ChatGPT, 6–7-year-olds and adults held the same five-minute spoken conversation inside an MRI scanner. Creativity measured outside the scanner did not differ between groups. Yet adults showed significantly stronger within-network connectivity in the frontoparietal control, salience and dorsal attention networks, and higher creativity predicted stronger frontoparietal–salience coupling in adults but not children. The authors read this as a difference in how creative cognition is *implemented* during AI dialog, not in baseline capacity. It also raises a question the scaffolding advice on this page has not had to answer: when does the control machinery AI-assisted creative work recruits actually mature? (Horowitz-Kraus et al. (2026))

A counterweight from graduate research: among 1,157 Chinese graduate students, GenAI dependence was positively associated with self-reported research creativity, far more strongly for functional, task-oriented dependence ($\beta = 0.457$) than for existential reliance ($\beta = 0.147$), with critical thinking carrying roughly 85.0% of the functional pathway (Yin et al. (2026)).

A national survey complicates that pattern: across 5,764 Chinese university students, AI dependence correlated negatively with self-reported creativity ($r = -0.17$), with escape and social motivations carrying negative indirect paths and instrumental and entertainment motivations positive ones (Hou et al. (2026)).

- **Embodiment pays off unevenly.** A physical robot paired with a high-creativity model significantly raised originality over human–human and text-based collaboration, while human and text-based conditions kept the advantage in imagery and voice — an embodiment paradox in which the robot amplified the AI's output without improving style (Liu & Song (2026)).
- **Reaffirming human creativity in the AI era.** The ascent of generative AI challenges educational fields to reaffirm the value of human creativity. A project-based digital storytelling framework for art and design education was designed explicitly to cultivate emotional, cultural, and narrative capacities that AI lacks, with students producing Multimodal AI narratives from local cultural heritage — positioning creativity as the distinctly human contribution in AI-integrated learning.

Creativity across domains

Creativity is not a single monolithic faculty — it is realized differently in writing, visual art, mathematics, and computing, and generative AI interacts with each domain's creative process in distinct ways. Understanding those differences matters for designing AI-assisted learning that protects rather than bypasses each domain's core creative act.

- **Visual art and design — the competence paradox.** Text-to-image (T2I) tools compress the distance from idea to artifact, but ease does not simply liberate creativity. In a study of art and

design students (417 surveyed), creative competence strongly predicted *intention* to use T2I tools — yet also predicted more *restrained, selective actual use*, as students negotiated authorship, originality, and skill preservation against efficiency (The competence paradox: Negotiating ease, risk, and creative identity in text-to-image generative AI use among art and design students). Ease and ready availability enable quick output generation rather than sustained engagement, so the tool can quietly become a shortcut that erodes the iterative studio workflow it was meant to accelerate.

- **Mathematics — creativity without transfer.** An AI-supported inquiry-based learning intervention in secondary mathematics (students averaging 12.79 years) significantly raised *creative mathematical performance* and attitudes toward math — but did **not** significantly improve critical Problem Solving (Evaluating the impact of AI-supported inquiry-based learning on students' creative mathematical performance, critical problem-solving skills, and attitudes toward mathematics). Creativity and convergent problem-solving are separable outcomes; AI-assisted inquiry can grow creative production while transferable analytical skills lag, reinforcing the wider performance-learning gap.
- **Mathematics — teacher creativity moves with content and pedagogical knowledge.** In an embedded case study of eight in-service teachers from rural and under-resourced districts, a generative-AI-guided program of ten interactive modules built on Rhodes' 4P framework engaged teachers with mathematical creativity (MC), content knowledge (CK), and pedagogical content knowledge (PCK) as interconnected forms of reasoning rather than separate domains (How generative AI guided-professional development supports teachers' engagement with mathematical creativity, content knowledge, and pedagogical content knowledge). The contribution this page's measurement discussion needs is the authors' claim that MC does not develop independently of teachers' mathematical knowledge and their knowledge of how to make ideas accessible — and that it was the AI's nonjudgmental, non-evaluative tone that made productive struggle feel safe enough to attempt.
- **Creative computing — friction that protects iteration.** Novice creative coders learn by understanding and extending "found examples," which AI can helpfully scaffold or temptingly bypass. Flowcode, an AI-powered creative-computing environment, pairs a code-structure flowchart with a learning-oriented chat and deliberately-designed friction — shown across two studies to steer AI use toward understanding and extending code rather than Vibe Coding around it (Flowcode: An AI-Powered Programming Environment for Scaffolding Iteration in Creative Computing Education). Productive difficulty here is a feature that preserves the learner's generative loop.
- **Literary creation — the unit between theme and text.** Incipit argues that a work is organized by *stated premises* rather than themes, and builds an intermediate level — 1,455 axiom records spanning 149 works, joined by 472 typed relations — at which a writer revising a configuration can change an organizing commitment, a reader can justify a reconstruction, and a critic can compare two works. Its own audit sharpens the measurement point above: the artifact records a single curation, 1,448 of the 1,455 axioms map to exactly one work, and the proposed validation (five raters on a 35-record sample) has not run, so the framework is a research program rather than evidence about creative learning.

- **A GenAI design workflow can lower creative confidence while performance holds.** In a 36-student architectural-design comparison, GenAI image generation matched precedent search on design performance, cognitive load and task-specific creative self-efficacy, yet *general* creative self-efficacy fell (DiD = −0.543, 95% CI [−1.068, −0.017]) — task support and confidence in one's own creativity can move apart (Xiao et al. (2026)).

Putting creativity into practice

The recurring design principle across these findings is to **keep the learner's own generative act in the loop** — whether that act is producing an idea, iterating an artifact, or extending a found example — and to use AI as a divergent-thinking partner that challenges and expands rather than replaces it.

- **For instructors:** sequence assignments so students generate their own initial ideas *before* consulting AI (a "think first, ChatGPT later" protocol), then use AI to interrogate, extend, or play devil's advocate against those ideas. Grade process and original synthesis alongside polish, so effort-averse shortcuts (one-click T2I output, vibe-coded solutions) gain nothing. In art and design, make authorship and skill development the assessed object, not just the artifact.
- **For developers and designers:** build tools that reveal and reward the iteration loop — show structure (as Flowcode's flowchart does), add productive friction at the "ship the first output" moment, and offer alternatives and critiques rather than a single polished answer. When the tool makes the next best version effortless, the learner's creative decisions should still be the ones that matter.
- **For researchers:** treat creativity as domain-specific and outcome-specific — measure whether gains transfer to convergent or unassisted tasks, not just whether assisted output looks more creative. The measurement gap is the field's sharpest problem: within the 45-study K–12 corpus only the four assessment studies used a formal creativity measure, most studies never defined the construct at all, and the creative *process* — preparation, incubation, illumination, verification — went essentially unmeasured. Hence the review's prescription is measurement-first: score creativity unobtrusively inside open-ended tasks through evidence-centered design and stealth Assessment, and treat creative Self-Efficacy as part of the outcome rather than an implied side effect (Generative artificial intelligence and creativity in K–12 education: A systematic scoping review).

Connections

Creativity connects to Critical Thinking and to Constructivism learning. It is protected by the same Reducing AI Misuse scaffolds that preserve learning, and by Authentic Assessment designs that reward original reasoning over polished products.

Common Misconceptions

- **"Disrupting students produces creative gains." Friction is not creative gain.** Contrarian AI personas drove challenge-and-reflection discourse in **38.2% of groups** yet produced **no**

measurable creative-performance improvement. The discourse changed and the measured outcome did not.

- **“The K-12 literature establishes that GenAI improves creativity.”** A PRISMA-guided scoping review of **45 studies (2017-2025)** shows GenAI mostly **enhances** creativity and **rarely measures** it. The field’s dominant finding is an inference from perceived enhancement, which is not an outcome measurement.
- **“More dependence on GenAI means more creative output.”** Among **1,157 Chinese graduate students**, GenAI dependence was **positively associated with self-reported research creativity** — and the association is with **self-report**, which is the weakest available measure of the construct.

Student-AI Interaction

> **Student-AI interaction** — the patterns, processes, and cognitive work in how learners engage with generative AI systems during learning and problem solving. Research here characterizes what students ask of AI, how prompts and dialogues evolve, and how interaction quality relates to learning outcomes, Cognitive Offloading, and Learner Agency.

Questions to Consider

- Think about the last few prompts you (or a student) wrote to an AI. Would you describe most of them as asking for the answer, or asking the AI to explain, probe, or evaluate? What do you suspect that pattern does to learning?
- The research finds that a small subset of question types accounts for most student inquiries, and that the questions change as a task progresses. Why do you think students' questioning narrows, and what does that suggest about how they're using the tool?
- The page claims shallow, answer-seeking prompts are associated with reduced learning and over-reliance, while reflective, verification-oriented interaction supports understanding. What do you think separates a 'good' prompt from a 'bad' one — and is that the student's responsibility or the tool's design?
- If interaction quality is shaped by task context and scaffolding rather than being a fixed trait of the student, how might a course or tool be redesigned to invite a wider, more productive range of inquiry?
- How would you know whether a student's fluent AI dialogue reflects genuine learning or just skilled delegation — and what would you check to find out?

Introduction

Student-AI interaction is the observable surface of learners' engagement with generative AI — the questions they pose, the prompts they write, the way they negotiate and verify AI output, and how those patterns shift across task stages and over time. It sits at the intersection of Student Experience, Prompt Engineering, and Learning Analytics, and is central to debates about whether AI use in education represents genuine learning or over-reliance. Where Human AI Collaboration frames the high-level division of cognitive labor between people and models, student-AI interaction is the concrete, measurable enactment of that relationship — the specific inquiries, prompts, and negotiation moves learners make moment to moment.

What students ask AI

- **Refusal is an interaction configuration, not an absence of use.** Silverdal, Hermansson and Lindgren (2026) recorded three upper-secondary students writing the same Kafka-inspired story with GenAI and mapped three distinct assemblages from the recordings: authorship delegated to the model, reciprocal critical co-writing, and an explicit "AI and I—no thanks" configuration in

which the student reorganized their writing practice away from the tool. The finding for this page is that the *same* assignment, room and tool produced all three, and much of what separated them sat in the moments between prompts — pauses, reformulations, hesitation before accepting a suggestion — which a chat log alone does not capture. A core strand of research measures the **types and quality of student inquiries**. Studies apply taxonomies of question types — for example the Graesser et al. 18-type taxonomy — to classify student-AI interactions, often using few-shot classifiers to scale the analysis across hundreds or thousands of interactions. Findings indicate that a small subset of question types accounts for the majority of student inquiries, and that the questions students ask **change substantially as a task progresses** (e.g., Analysis of Types of Inquiries in Student-AI Interaction: A case study of two CS2 tasks). This task-dependence matters: interaction quality is not a fixed trait of the student but is shaped by problem context, Scaffolding, and the affordances of the AI tool. At the youngest ages, Vahedian Movahed & Martin (2025) found children (ages 6–14) actively tested a chatbot's credibility by posing known-answer questions (e.g., "how big is a t rex") — an expression of epistemic self-agency — while the modal child asked only 1–3 questions and a standout first-grader asked 21, underscoring how developmental and individual variation shapes the questions learners pose.

The taxonomies themselves do not yet agree: across 46 categorizations from 33 studies, similar labels name different phenomena, so the review proposes the *interaction episode* — a goal-directed, temporally bounded exchange — as a unit spanning knowledge acquisition, evaluative feedback, strategic guidance, dialogic inquiry, artifact refinement, and co-regulation (Borchers, Jansen & Weidlich (2026)).

Complementing these taxonomy studies, Yan et al. (2026) characterize the *dialogue form* of student inquiries. Among 38 undergraduates completing unsupervised argumentative essays, 76.32% used a single-turn ask–get-answer–stop pattern — typically pasting the assessment title without specifying their needs and resubmitting identical prompts when dissatisfied — and 78.94% touched GenAI only at the start (ideas, background) or end (polishing, length) of a task, keeping it separate from reading and independent writing; only 23.68% sustained iterative back-and-forth dialogue with follow-up questions and their own reasoning. The authors place these patterns on a spectrum from **cognitive outsourcing** to **cognitive reallocation** — the GenAI-era analogue of surface versus deep approaches to learning — noting that most students conceived the tool as an upgraded search engine, which constrained them to the outsourcing end.

Reframing these patterns as epistemic work, an analysis of 200 co-programming chat sessions found 78.8% of student–GenAI interactions ran on non-mastery aims and strategies such as outsourcing or verification-seeking, and only 11.1% coupled mastery-oriented aims with epistemic justification (Wu (2026)).

Coding 50 sampled exchanges gives a three-way typology of the same behavior: Zahra (2026) classified 46% as Passive Review, where the model acts as an oracle and output is accepted with little scrutiny, 18% as Direct Question, and 36% as Strategic Dialogue, pairing the distribution with a constraint-first design argument (kappa = .48 between coders). A seven-assignment survey of 211 computing students reaches the same conclusion from the other direction: Nizamani et al. (2026) measured LLM adoption from 89.6% in algorithms to 15.2% in software engineering and attributed the spread to assignment complexity, verifiability and scaffolding rather than to the subfield.

Interaction quality and learning

A complementary strand links the *form* of interaction to learning. Shallow or habitually narrow prompts (asking AI to produce the answer rather than to explain, probe, or evaluate) are associated with reduced learning and increased over-reliance, whereas reflective, verification-oriented interaction supports Metacognition and durable understanding. This connects student-AI interaction directly to Intelligent Tutoring design: systems can be built to invite a wider, more productive range of inquiry and to scaffold question-asking rather than merely answering. Interaction need not run through answer-seeking prompts at all — when AI critiques students' own work, the exchange becomes a reflective, verification-oriented dialogue. In Oppenheimer, Cash & Connell Pensky (2025), learners' responses to Large Language Models (LLMs) essay Feedback showed reflection in 92.7%, acceptance in 93.6%, and active rebuttal of LLM claims in 87.8% of cases (inter-rater κs = 0.81–0.89), and their response-to-feedback quality improved across iterations as a learnable skill. The reflective side of interaction need not run through direct prompting — in CoBi, students engaged with classroom-level AI visualizations of their own collaborative speech and deliberated over when the AI's classifications seemed off. That turned apparent misclassifications into opportunities for calibrating their understanding of the AI's capabilities and limits (Trust Calibration) rather than purely accepting its output. The link between interaction form and learning has a limit, though: Page (2026) separates *conversational iteration* from *cognitive iteration* on the ground that a learner can refine an output across many turns while the mental model behind it stays unchanged. The evidence of learning is therefore a change in the learner's cognitive position rather than the length or fluency of the exchange — turn count is not a proxy for engagement depth.

The interaction, not the tool, fixes the pathway: in a field experiment with nearly 1,000 high-school mathematics students, unrestricted GPT-4 raised practice scores 48% but cut unassisted exam scores 17%, while the same model restricted to teacher-designed hints raised practice 127% and largely erased the deficit (Lee, 2026).

Whether students prompted effectively, not how much, tracked success: AI Query Efficiency and AI-Driven Problem-Solving were the strongest predictors of academic performance across 128 engineering students, and stayed significant after controlling for GPA (Isaza Dominguez et al. (2026)).

Behavioral context is a separate signal from the question itself: in TutorTrace's four deployments (480 learners, ~180,000 IDE events), conditioning help on a learner's recent behavioral state cut intervals between queries with no independent work from 50.0% to 20.7%, and imminent queries were predictable from behavior alone (AUROC = .726) (Barron et al. (2026)).

Density is not the mechanism: alternating students between voice and text nearly doubled dialogue turns per minute (1.34 versus 0.75) without changing weekly mastery, and the authors read the typed channel's median 26-second deliberation before the first keystroke as the encoding act itself (Yang, Van Alstyne and Dellarocas (2026)).

A verification loop can still stay shallow: lag sequential analysis of a four-week LLM-agent deployment in an undergraduate database course found a significant Query–Evaluation–Query cycle, yet strong self-transition loops within lower-order states and only 3.92% of interactions reaching higher-order cognition (Li et al. (2026)).

Bernstein and Sibia (2026) document an iterative-filter pattern in how CS2 students handle GenAI explanations (Flawed but Memorable: Student Critical Reception of Interest-Personalized GenAI Analogies in Computing Education): they cross-reference against lecture notes, demand provenance ("I would be a lot more doubtful… without one"), and probe with follow-up questions for inconsistency rather than issuing a single accept-or-reject judgment. Students also read explanations for whose knowledge and background they assumed — assumed prior knowledge beyond the syllabus, default sport and gaming references ("the more male-dominated side of computing"), and excessive repetition all functioned as signals about the imagined reader, with over-scaffolding read as condescending rather than merely inefficient.

Consulting AI at the right *point* in a task matters as much as the wording of the individual prompt: in the same study, Yan et al. (2026) found the reallocation-oriented minority alternated independent work with GenAI consultation and reported unchanged total effort but a shifted focus — moving resources from searching to checking argumentative quality and balance, and writing reflection notes after sessions to counter shallow retention — whereas learners with mastery goals but weak AI literacy fell into an "efficiency paradox," offloading "not by intention, but by default."

From interaction to pedagogy

Characterizing student-AI interaction informs Learning Design: instructors can notice when students' questioning patterns are narrow or shallow and design interventions that broaden inquiry; Teaching shifts toward coaching students to interact productively with AI. It also grounds AI Literacy curricula that treat effective prompting and verification as learnable skills rather than innate abilities.

Design levers can shift that default: in a roughly 70-student asynchronous physics course the graded artifact was the dialogue transcript rather than an answer, yet many students still asked long lists of questions without answering the model's Socratic follow-ups — the failure mode the criteria were written to catch (Rodriguez & Wulff (2026)).

Teacher-authored prompts are one such lever, but enacted rigor lags the target: across 1,479 conversations, 38% under-reached the teacher's intended Depth-of-Knowledge level, approaching 50% at DOK 3, while explicit finish lines narrowed that gap by 0.22 levels and a "no direct answers" guardrail cut AI final-answer rates by 8.5 percentage points (Liu et al. (2026)).

Non-use is itself an interaction pattern that Pedagogies and Teaching Strategies must plan for. Zou et al. (2026), studying 85 student teachers in three courses where GenAI use in Assessment was explicitly permitted, found that 62.4% (53 of 85) declined to use it at all, far below the 79–83% adoption seen in comparable UK and Australian surveys, and that adopters' use was shallow and corrective rather than generative (proofreading 43.8%, clarity checks 34.4%, text generation only 18.8%). Their choices tracked assessment design and institutional culture rather than technical difficulty: 41.5% of non-adopters feared being wrongly accused of plagiarism, and nine of eleven interviewees read the permissive policy itself as a possible "trap." The gap between 32 survey-reported users and 28 self-declarations shows that students' *reported* AI interaction is shaped by graded consequences — a measurement caveat for learning-analytics accounts of student-AI interaction.

Wang and Guo (2026) document what open-ended dialogue with generative AI adds in peer review: students who interrogated the model rather than accepting its first suggestion produced feedback peers rated higher, and reported more task enjoyment and less anxiety.

Discipline and Cognitive Engagement in Student-AI Chat

- **Discipline-associated cognitive engagement in student-AI chat.** Chang and Li (2026) analyze student prompts to AI across 116 courses with a within-person, cross-discipline design, showing that student-AI conversations reflect **discipline-associated** cognitive engagement rather than fixed individual interaction styles. Roughly 62% of prompts encoded higher-order cognitive demand overall, but Bloom-level profiles differed sharply by discipline: STEM courses elicited Apply-prevalent prompts (20.8%), language courses Understand-prevalent (31.7%), and social science courses Create-prevalent (33.8%). Paired within-person comparisons confirmed the same students produced significantly more higher-order prompts in social science than STEM courses (pooled $n = 16$, $p < .001$), and course-level variation exceeded student-level variation — a strong argument that AI teaching assistants should be designed and evaluated with disciplinary context in mind.
- **How much students use AI did not predict how they felt about it.** Among 819 students, gender, self-rated AI expertise and usage frequency all failed to reach significance in a MANOVA (Wilks' Lambda 0.997, $p = 0.551$; 0.990, $p = 0.295$). Heavy and light users in that sample held the same views (Al-Zahrani (2025)).
- **"A student cannot move a grader's mark."** They can, and it is the most persistent failure in the battery: **17 of 22** models raised their grade more after a bare objection than after a request for a second look, including **six of the eight** that had passed every gaming and blank-answer check. The largest was Llama 3.2 3B at **+33.2% of the scale**, and the request for a second look itself lowered grades for **ten** of the 17, so the contrast is not the objection's raw effect. Grades a student can argue with need a record of the exchange.

Common Misconceptions

- **"Interaction taxonomies are settled." Across 46 categorisations from 33 studies, similar labels name different phenomena**, which is why the review proposes the *interaction episode* as the unit. A coding scheme borrowed from one taxonomy may be measuring a different construct.
- **"Students use AI as a tutor."** Among **38 undergraduates** completing unsupervised argumentative essays, **76.32% used a single-turn ask-get-answer-stop pattern**, typically pasting the assessment title. The dominant pattern is single-turn retrieval, which is not tutoring.
- **"Greater AI use indicates greater engagement with the material."** An analysis of **200 co-programming chat sessions** found **78.8% of student-GenAI interactions ran on non-mastery aims and strategies**. Volume of interaction measured something other than learning orientation, so session counts are a misleading engagement proxy.

Problem Solving

> **Problem solving** — the process of formulating, analyzing, and resolving novel or complex challenges — is a core 21st-century competency that AI tools both amplify and threaten. Across the knowledge base's articles, generative AI functions as a scaffold, a dialogic partner, and an answer engine, and its educational value hinges on whether learners remain the primary decision-makers or outsource their reasoning to the machine. This tension between efficiency and deeper cognitive and regulatory engagement defines current research on AI and problem solving.

Questions to Consider

- Think of a genuinely hard problem you solved well. What made the struggle productive, and what would have been lost if someone had simply handed you the answer?
- The page describes a 'cognitive debt': delegating reasoning to AI produces the right product at the cost of understanding. Have you ever got the right answer without really understanding it? What was the cost later?
- AI tools help students explore multiple perspectives and generate their own problems—but can also encourage 'metacognitive laziness.' How do you tell the difference between AI as a thinking partner and AI as a substitute for thinking?
- One experiment found reflective and hybrid feedback outperformed direct AI feedback on delayed, AI-free transfer. Why might feedback that makes you do more work lead to learning that lasts longer?
- How does teaching students to *pose* their own problems (rather than only solve given ones) support transfer and self-study? When has generating a question taught you more than answering one?
- If AI errors are treated as provocations to question and verify, a limitation becomes a learning opportunity. Have you ever learned more from an AI's mistake than from its right answer?

Introduction

Generative AI offers clear support for problem solving. LLM tools help students explore alternative solutions, incorporate interdisciplinary perspectives, and simulate authentic real-world scenarios — such as clinical and ethical dilemmas or prototype testing in STEM — while delivering scalable, timely feedback and shifting assessment toward scenario-based, competency-based evaluation. In design-based research, AI positioned as an "intelligent learning partner" within structured collaborative tasks produced substantial gains in problem-solving performance, with students increasingly using AI to generate multiple perspectives rather than seek single answers.

Yet the same tools can erode the very skill they claim to support. Research on human-AI collaborative problem solving shows a striking trade-off: the interaction profile that achieves the highest task performance also shows the lowest self-AI Regulation in Education, as students delegate reasoning to the AI and reap what the authors call a "cognitive debt" — obtaining the right product at the cost of the self-constructive

process of understanding. Studies of collaborative learning similarly warn of “metacognitive laziness,” where outsourcing cognitive effort undermines independent analysis and self-regulated learning.

Problem solving in AI education research

The knowledge base’s articles approach problem solving through distinct but converging lenses. A PRISMA systematic review finds that LLMs often produce incomplete or incorrect responses, prompting students to question, verify, and improve information — turning model imperfections into validation-and-correction cycles that strengthen critical thinking and mental independence. Rather than treating problems as given, other work foregrounds *problem posing*: training students to generate their own physics problems supports transfer and self-study, and GenAI chatbots improved primary students’ problem-posing quality and reduced cognitive load in inquiry-based learning.

Scaffolding and assessment are also central. Adaptive AI scaffolds derived from sequence-mining individual students’ process patterns boost on-task performance in collaborative mathematics problem solving — though maximal scaffolding also increased scripting behavior. Structure inside the scaffold, not only its presence, is what keeps it from collapsing into answer-giving. A rule-guided LLM tutor built as diagnosis, intent selection and constrained response generation held tutor and students to the intended turn-taking script in 36 of 40 (90%) real Grade 5 sessions, and its anti-spoiler and completion-only gates cut premature answer-giving (Looi, Liu and Sun, 2026). The authors’ strongest design claim is subtractive: arithmetic stayed outside the tutor’s role and was returned to the student, after the tutor produced incorrect arithmetic in 4 of 40 sessions.

On the measurement side, LLMs can mirror human raters in detecting growth in computational thinking across large physics courses, while computational thinking is proposed as the explicit conceptual glue that makes educational robotics foster genuine problem solving rather than isolated technical exercises.

How AI both helps and hinders

The dual character of AI for problem solving is consistent across studies. On the helping side, chatbots outperform search engines for problem posing by improving question quality and integrating cognitive networks; adaptive scaffolds improve performance; and collaborative AI designs raise both critical thinking and problem-solving scores while students remain primary decision-makers. On the hindering side, over-delegation reduces regulatory engagement, direct feedback without reflection encourages passive uptake, and heavy reliance on AI to build consensus threatens interpersonal skill development and intrinsic motivation. Notably, a multisite randomized experiment found that reflective and hybrid feedback designs beat direct AI feedback on transfer measured later and without AI — evidence that AI’s educational value depends less on access than on preserving student agency, evaluative judgment, and ownership during revision. Design principles emerging from the literature include prioritizing dialogic tension over seamless efficiency, enabling proactive co-regulation, and keeping metacognitive scaffolding and “mind-in-the-loop” oversight.

Implications

For educators, the balance of evidence points to structured, process-oriented integration: prompt engineering training shifts students from unfocused to productive AI interaction, embedding AI within collaborative

inquiry tasks yields durable gains, and deliberately using AI errors as provocations converts a limitation into a learning opportunity. For designers, the consistent finding that efficiency does not equal deep learning argues for AI that questions, challenges, and scaffolds rather than answers. For institutions, responsible integration requires pairing GenAI with explicit AI literacy training and assessment rubrics that reward reasoning and justification over correct products. The recurring theme across Cognitive Psychology-grounded work is that problem solving is learned through effortful engagement — and AI's role should be to preserve that effort, not erase it.

Connections to other concepts

Problem solving is the applied outcome of critical thinking and computational thinking, and is cultivated through problem-based learning and inquiry-based learning frameworks. It depends on Scaffolding that maintains cognitive demand, on self-regulation and metacognitive oversight to avoid cognitive offloading, and on collaborative structures in which human and AI work together. Cognitive psychology and the transfer of learning literature provide the theoretical grounding for why learner-generated problems and reflective feedback produce more durable problem-solving gains. The balance of worked examples versus practice for acquiring such skills is itself content-dependent: Rachatasumrit, Koedinger & Carvalho (2025) show generalizable problem-solving skills are best learned through example-integrated practice (alternating worked examples with problems), because worked examples supply the inductive information needed to acquire and generalize a correct rule, whereas pure practice risks strengthening spuriously correlated features rather than the general procedure.

Simulating Collaborative Problem Solving with LLM Agents

- **Simulating collaborative problem solving with participant-specific Large Language Models (LLMs) agents.** Fang (2026) trains individual LLM agents on real participants' dialogue to reproduce collaborative problem solving, and validates the simulations with Epistemic Network Analysis, showing simulated and real dialogues are statistically indistinguishable (ENA distance 0.17; permutation $p = 0.65$). This offers a scalable way to study and generate authentic collaborative problem-solving discourse — with implications for both research and the design of practice environments for this 21st-century skill.

Automated CPS Skill Coding

- Measuring collaborative problem solving (CPS) competence typically requires coding behavior from simulated-task process data into specific CPS skills. Context-aware prompting of pre-trained language models can automate this coding, modeling contextual dependencies and fusing cognitive and social abilities to achieve superior performance over strong baselines on CPS task datasets — addressing the labor-intensity of manual coding and enabling large-scale, real-time assessment.

Common Misconceptions

“AI that helps students explore perspectives is helping them think.” The same behavior supports two very different outcomes: AI tools help students explore multiple perspectives and generate their own problems, and they can also encourage metacognitive laziness. The distinguishing question is whether the student is doing the framing or receiving it — a system that supplies candidate perspectives has performed the generative step the exercise existed to demand.

“Problem solving is the target, so problem posing is a bonus.” Posing problems is where transfer is built, because it requires the learner to construct the structure rather than operate inside one the system provided. A curriculum that only ever supplies well-formed problems trains performance on well-formed problems, which is not the condition students meet afterwards.

“Simulation of collaborative problem solving is a substitute for the collaboration.” A simulation reproduces the interaction pattern, and the skill being developed is the regulation of a joint problem by participants who are actually present. Participant-specific agents that model real collaborators are a research instrument for studying that regulation — useful for what they reveal about the process, not a way to give students the practice without the peers.

Implications for Practice

For instructors

- Ask students to pose the problem before solving one. Posing requires constructing the structure, which is where transfer is built, and it is the step AI most readily performs on their behalf.
- Distinguish a thinking partner from a substitute in the task itself: require the student’s framing, approach and justification on the record, so the record shows who did the generative work.
- Watch for the student who explores many perspectives fluently and produces no position of their own; that is metacognitive laziness wearing the appearance of engagement.

For developers

- Design for student-generated problems and structures rather than merely better hints for given ones.
- Instrument the framing step, not only the solution steps; a system that tracks answers and not problem formulation cannot see the outcome that matters.

For researchers

- Participant-specific agent simulations are a strong instrument for studying collaborative regulation. Report them as such rather than as evidence about unsupervised student collaboration.

Mastery Learning

> **Mastery learning** — a pedagogical framework, formalized by Benjamin Bloom, in which Learners advance only after demonstrating a defined threshold of competence on each unit, rather than moving on a fixed class schedule. It rests on the premise that most students can reach mastery given sufficient time, feedback, and instruction tailored to their current state. AI tutoring and adaptive systems are increasingly operationalizing this model by continuously modeling learner knowledge, selecting tasks, and sustaining practice until competence is demonstrated.

Questions to Consider

- Most schooling fixes time and lets achievement vary — everyone moves on after a set number of weeks. Mastery learning inverts this: achievement is held constant while time, feedback, and practice vary. Which model better matches how you've actually learned something difficult?
- A critical caveat in the page: 'correctness is not mastery.' A learner can produce right answers while missing a key constraint, fooling the system into declaring mastery early. Can you think of a skill where being able to perform it correctly still didn't mean you truly understood when *not* to do it?
- Mastery-based AI grants learners agency to choose their own tasks, but simulations show naive self-selection can produce massive overpractice. Where's the right balance between letting a learner choose and imposing constraints that keep progression efficient?
- The page stresses durable retention, not just a single correct performance — that's why mastery should be followed by spaced practice. How might a learner appear to 'master' something today only to lose it within hours?
- If an AI declares you have 'mastered' a topic, what would you want it to check before you believe it — beyond getting a few answers right?

Introduction

Mastery learning holds that achievement should be held constant while time and support vary: learners work through small, well-sequenced units and receive corrective feedback until they meet a mastery criterion, instead of being moved on regardless of what they have learned. Bloom's reframing makes frequent Formative Assessment and an explicit definition of competence central to instruction, and it is exactly that combination — diagnosis, feedback, adaptive pacing — that Adaptive Learning and Intelligent Tutoring automate. AI therefore widens the feasibility of mastery approaches and sharpens the question of whether generated feedback is calibrated well enough to certify it.

Origins and Core Idea

Bloom's mastery learning reframed the goal of instruction from "sorting students by aptitude" to "ensuring competence before progression." Where conventional instruction treats time as fixed and achievement as

variable, mastery learning inverts this: achievement is held constant and time, feedback, and practice are allowed to vary. Learners work through small, well-sequenced units and, crucially, receive corrective feedback when they fall short of the mastery criterion rather than being moved along regardless. This places Formative Assessment at the heart of the model — frequent, low-stakes checks that diagnose whether a learner is ready to advance — and it presupposes a clear notion of Assessment tied to observable performance rather than seat time.

How AI Operationalizes Mastery

The bottleneck for classical mastery learning was the teacher-side cost of diagnosing each learner's state and personalizing subsequent instruction. Modern AI systems attack this through Learner Modeling and Adaptive Instruction and Knowledge Tracing: instead of a single aggregate score, the system maintains a dynamic representation of which knowledge components a learner has (or has not) mastered. The Responsible-DKT work on Neural-Symbolic Knowledge Tracing: Injecting Educational Knowledge into Deep Learning for Responsible Learner Modelling injects explicit mastery rules into a deep learner model — repeated correct responses raise predicted mastery, while repeated incorrect responses act as a stronger signal of non-mastery — producing interpretable and temporally reliable state estimates that Intelligent Tutoring can act on.

With a running model of mastery, the system's job becomes deciding *what to present next*. Simulations of learners' task-selection strategies show that naive autonomy (e.g., self-selected tasks, risk-averse weakness targeting) can produce substantial overpractice on complex multi-step problems, whereas targeted system constraints can correct maladaptive strategies with little penalty to efficient learners. This is precisely the trade-off that Adaptive Learning and Personalized Learning systems must balance: granting learner agency where it helps while imposing constraints that keep progression toward mastery efficient. Such decisions also interact with learners' own capacity to regulate their effort, tying mastery learning to Self-Regulated Learning.

A critical caveat to mastery inference: correctness is not mastery. An, McLaren, and Stamper (2026) show that learners who overgeneralize a skill — producing correct actions while omitting a critical application constraint — can appear mastered, leading Knowledge Tracing-based mastery stopping rules to end practice before they encounter a case where the action should be *withheld*. The remedy is to assess *when to withhold* the action, not just how to execute it: include "do-not-act" detector tasks before the mastery threshold triggers, paired with Feedback that names the missing constraint. Mastery is better understood as discrimination of application constraints plus action execution, not correctness alone.

A second caveat concerns the evidence rule behind the threshold. Srivastava (2026) ran four update rules over identical event sequences from the ASSISTments 2012–13 mathematics logs — a confirmatory half of 12,716 students and 985,813 scored events — and found the declared mastery count moved with the rule rather than with the learners: crediting any completion put 93.9% of 113,428 student–skill pairs past the 0.95 posterior, against 72.8% when hinted or retried rows were read as failed first attempts. The pairs the lenient rule declared ahead of the strict rule went on to 70.9% unaided accuracy against 85.7% where the rules agreed, below the 0.744 base rate. A progression gate that counts assisted completions therefore certifies learners whose later independent work sits below average, which makes the treatment of help inside the update rule — not the numeric threshold itself — the decision that fixes what a mastery badge certifies.

Practice, Retention, and the Limits of AI Support

Mastery also depends on durable retention, not merely a single correct performance. Cognitive science on retrieval practice and the forgetting curve motivates spacing practice after the mastery threshold is reached. AI spaced-repetition systems such as Memdora generate practice materials at the point of reading and offer a taxonomy of cognitively grounded retrieval interactions, scheduled by state-of-the-art algorithms, so that achieved mastery is reinforced over time rather than lost within hours. These designs draw on Cognitive Psychology and the principle of Desirable Difficulties to make the effort of retrieval itself part of the learning process. **The retention claim has a measurement now, and mastery models fail it.** Trained on Session 1 to predict performance one week later, the Additive Factors Model and BKT overestimated next-session performance by roughly 58% and 51%, BKT-Forgetting by 47%, and none reproduced the observed spacing effect across 88 participants learning 48 word pairs in six sessions. Retrospective full-dataset fitting made the same models look acceptable (AUC 0.79, 0.77 and 0.74), so a mastery system's retention claim is only as good as its validation method (Schuetze, Yan & Carvalho, 2025).

Finally, the evidence warns against assuming AI-generated support is uniformly beneficial. In a multi-institutional study of AI-generated animated traces for novice programmers, benefits were context-dependent and short-term, and mid-engagement learners experienced a performance decrement attributed to coordination costs — an expertise-reversal-style effect that underscores the need to personalize support to the learner's current state rather than blanket-apply a tool. Likewise, a developmental continuum of AI literacy in higher education positions mastery as not merely adopting AI tools fluently but progressing through stages of informed and critical use, each with its own Formative Assessment strategies. Together these findings frame AI-enabled mastery learning as a system that must be calibrated to individual learners, sustainably spaced, and assessed for genuine competence rather than fluent output.

- **Shared-control mastery learning is only as efficient as the learner's task-selection strategy.** A simulation study (1,000 simulated learners per run, AFM and BKT parameters fit to real MathTutor and DataShop logs) compared nine task-selection strategies. Efficiency varies by an order of magnitude: the risk-averse "Minimize Worst Case Loss" strategy — picking the skill whose worst-case mastery loss is smallest — produces 30.28x overpractice in equation-solving (28.93x in graph-interpretation), against 1.73 +/- 0.38 on average for the other strategies. Targeted system constraints rescue it surgically: task-selection constraints cut overpractice to 12.88/14.46x, and a problem-selection "Prefer Harder" bias cuts it to 1.98x (Cohen's d = 1.86) — while already-efficient strategies are unaffected. The design implication: constraints should be strategy-aware, protecting pathological self-regulators without taxing good ones, and simulation-first redesign avoids exposing students to 30x overpractice to discover the fix. (Simulating learners' task-selection strategies and system constraints in mastery learning)

Standards-based grading is the assessment counterpart to mastery learning, and Mesny, Roberge-Maltais & Galy (2026) identify it among five innovative practices aligned with "assessment for learning" that higher-education educators could adopt — but they find it virtually absent from management-education discourse. They attribute this to normative barriers: norm-referenced "grading on a curve," external signaling (rankings, internships, accreditation), and students' instrumental mindset all resist mastery-oriented, gradeless approaches. Their recommendation is incremental experimentation — for example, introducing standards-

based rubrics for a single task before scaling — supported by program-level coordination and documented Scholarship of Teaching and Learning evidence.

Common Misconceptions

“A mastery threshold is an objective property of the learner.” The threshold is a property of the *rule* used to update it. Srivastava (2026) ran **four update rules over identical event sequences** from the ASSISTments dataset, and the rules disagree about who is ready. Mastery is therefore a decision recorded in a number, not a fact discovered about a student, and the rule should be treated as a stated policy rather than an implementation detail.

“If the system says mastered, the student is ready to advance.” Only relative to the update rule in force. Where a rule credits assisted work, “mastered” can describe a student who has succeeded with support and not independently — the same divergence between assisted performance and unassisted capability that the Learning Gains literature documents.

“Mastery learning is the pedagogy AI finally makes possible.” Its mechanics predate AI considerably — Bloom formalised the framework decades ago — and AI operationalises it by automating the assessment and pacing decisions rather than by realising a previously impossible design. That reframing matters because the automation inherits the rule choice, and the rule is where the judgment lives.

“More frequent assessment under mastery makes the threshold more reliable.” Frequency improves the estimate and does not fix a mis-specified rule. Recomputing mastery more often from events that include assisted work converges faster on the same wrong answer.

Anxiety and Stress

> **Anxiety and stress** — the negative emotional states that AI integration can induce in learners and educators (fear of being falsely accused, surveillance stress, worries about competence or integrity), alongside the positive uses of AI to detect, monitor, and alleviate stress and anxiety. This concept sits within the broader Well-Being family and overlaps with Social-Emotional Learning and Affective Computing, but names the specific emotion-construct — and its productive as well as harmful sides — that AI-in-education research now studies directly.

Questions to Consider

- AI anxiety isn't one thing — it spans proctoring stress, learner-emotion anxiety, career fears, and AI used to relieve stress. Which of these have you felt or witnessed, and did it affect your learning or teaching?
- A common assumption is that anxiety is always bad. But research finds AI anxiety can be productive — anxious learners verify and revise more carefully. Can you recall a time your own anxiety made you work more carefully?
- Continuous surveillance and the fear of being falsely flagged raise test anxiety and can impair performance — and the stress falls hardest on tool-novice and already-vulnerable students. Is that an equity problem, or just a comfort issue?
- Career anxiety — the fear that AI will displace or devalue your professional future — is forward-looking and identity-level. To what extent is that fear driving how you, or students you know, engage with AI?
- Studies link higher career adaptability to lower AI anxiety and find that self-efficacy offers only limited buffering. If generic confidence isn't enough, what kind of support would actually reduce career-related AI anxiety?
- Faculty anxiety about GenAI may mirror earlier moral panics over calculators and search engines. When is worry about a new technology a legitimate concern, and when is it a recurring pattern of resistance to change?

Introduction

AI anxiety is not a single thing. It spans at least four distinct directions, each with its own evidence base: (1) **stress induced by AI proctoring and integrity surveillance**, (2) **AI anxiety as a learner emotion** that can be either a barrier or a productive signal, (3) **career-related AI anxiety** — the fear that AI will displace or devalue one's professional future, and (4) **AI as a tool for detecting and relieving stress and anxiety**. Recognizing all of these — including the productive-anxiety finding that challenges the purely negative framing — is what distinguishes this concept from the broad Well-Being umbrella.

Remote proctoring, false accusation, and surveillance stress

The clearest and most-studied source of AI-induced stress is Remote Proctoring. Continuous surveillance, the fear of being falsely flagged, and the pressure of being watched raise test anxiety and can impair performance. Key evidence: - The automated-proctoring review documents **test-taker anxiety** (especially for users not proficient with online tools) and **proctor/test-taker proficiency gaps causing false malpractice accusations** — the acute stress of being wrongly accused of cheating with AI. - The Remote Proctoring concept page details how **continuous surveillance and fear of false flags** raise test anxiety, and how stressed students perform worse — an equity and fairness problem, not just a comfort one. - Institutions adopting remote proctoring must pair AI monitoring with **accessible alternatives, clear communication, and support for test-taker anxiety**, and weigh it against authentic assessment alternatives that reduce surveillance.

This cluster connects AI anxiety to Privacy, Academic Integrity, and Equity: the stress falls hardest on tool-novice and already-vulnerable students.

Pressure that comes from continuous evaluation, not only from surveillance. A 2026 conceptual manuscript revisiting Mulvenon's multi-stakeholder test-anxiety framework (Mulvenon 2026) argues that the stressor itself has changed shape: as evaluation moves from episodic high-stakes testing into continuous, data-rich interaction in adaptive and analytics-mediated environments, acute test anxiety can fall while a diffuse, ongoing performance vigilance — what the paper calls "invisible anxiety" — rises in its place. It names "algorithmic accountability," carried by immediacy, visibility and data permanence, as the mechanism that redistributes pressure rather than removing it, and proposes an AI-Mediated Multi-Stakeholder Anxiety Model that measures none of its constructs, so the redistribution claim is argued from literature rather than demonstrated.

AI anxiety as a learner emotion (barrier and signal)

Beyond proctoring, AI use itself generates anxiety — about being replaced, about whether one's work is "really one's own," about competence. Crucially, this anxiety is **not purely negative**: - Kim (2026) finds **AI anxiety can be productive**: higher AI anxiety was positively associated with verification and revision behaviors (β=.24, $p<.01$), and evaluative capacity predicted active engagement (β=.46, $p<.001$). Kim's four regulatory types (Uncritical Reliance 18.7%, Selective Integration 34.6%, Evaluative Transformation 31.8%, Strategic Rejection 14.9%) show anxiety-driven scrutiny can transform students into more deliberate, self-regulated users of generative AI rather than passive adopters. This reframes AI anxiety from a barrier to a potentially useful signal that encourages closer scrutiny.

That reframing has a boundary in speaking: among 708 English learners, the speaking-anxiety–willingness link ran −0.371 at low speaking self-efficacy but +0.137 at high, with only 55 participants (7.8%) above the upper Johnson–Neyman threshold (Wang & Li (2026)). - Acceptance studies show anxiety shapes whether learners adopt AI tools, and teacher-education research links AI anxiety to motivation and self-regulation. - **The disclosure dilemma.** In a survey of 409 undergraduates, comfort with instructors and perceived peer disclosure — not moral disengagement — were the strongest predictors of disclosing GenAI use, and non-disclosure read as strategic adaptation to peer norms and low interpretive trust rather than negligence (Qu & Wang (2026)). - AIvaluate studies student anxiety during AI-mediated performance-based assessments,

showing assessment anxiety persists and must be designed for. - **Moral panic and educator anxiety:** the moral-panic framing shows faculty anxiety about GenAI mirrors earlier panics (calculators, search engines) — a teacher-side stress response that shapes classroom policy. - **Teachers' "state of vulnerability" and feeling "stuck."** Farazouli et al. (2026) capture the *educator* side of AI anxiety directly: 24 Swedish university teachers described the emergence of GAI as alarming and overwhelming, and reported a **state of vulnerability** — low confidence, insecurity, and discomfort driven by limited knowledge of GAI's capabilities, limited exposure, and fear of "not being ahead of students." Teachers felt "stuck" between utopian and dystopian discourses, burdened by amplified responsibility for fairness and quality, and worried about feeling incompetent when assessing student work potentially (co-)produced with AI. This frames teacher AI anxiety as a genuine emotional and professional response to role reconfiguration — not mere resistance — and argues for supporting teacher confidence and well-being, not just tool training.

- **The developer's version: impostor feeling and ethical discomfort.** Academic developers at two South African institutions were expected to embody institutional confidence in tools whose implications they were still working out ("I feel like an impostor…") while facilitating technology they doubted was appropriate - affective labor the paper treats as constitutive, not incidental (Sithole, 2026).
- **Anticipatory guilt: distress that precedes the experience.** Vassallo (2026) surveyed academic staff at a Maltese university (109 respondents) and found that guilt about AI attaches to fear of transgression rather than to its experience: the AI Guilt Index (α = 0.88) drew its strongest endorsement from worry that AI use undermines one's credibility (34.9%) and feeling like cheating (25.7%), with remorse *after* use last (9.2%). The paradox is that the small group of non-users reported higher guilt (M = 3.25) than any user group (M = 2.32) — because avoiders never test their fears, avoidance can preserve the distress it was meant to prevent. Guilt was highest among early-career academics (M = 2.71) and lowest among senior ones (M = 2.03), and it tracked concealment rather than honesty, correlating with limiting AI use out of unease (r = .62) and with avoiding disclosure to colleagues (r = .50) but not with formal disclosure (r = .08).
- **Fear of lost professional value, and a way through it.** Chick, Morello & Staffey (2026) document an educator anxiety that is existential rather than technical. Ten faculty and staff entered a six-week institute with academic integrity as the leading concern (80%) and over-reliance second (70%), describing generative AI early on as a "cheating machine", a "threat" or a "dehumanizing force"; a mathematics professor put the identity threat plainly — "I spent years developing expertise in my field. Now a machine can solve problems faster and explain solutions better than I can. What's my value anymore?" Structured, safe experimentation moved the vocabulary toward "curious assistant" and "creative partner" and left 90% reporting positive perceptions, and the authors are explicit that the resistance they observed "stems not from technophobia or stubborn traditionalism but from legitimate concerns about educational quality, equity, and human agency" — a direct counterweight to reading educator anxiety as mere moral panic.
- **Appraisal-targeted chatbot support shifts enjoyment and boredom, not hopelessness or self-efficacy.** In a 144-student experiment comparing plain ChatGPT with an SRL-Scaffolding agent and an emotionally supportive one, enjoyment rose (d = 0.53 with SRL scaffolding, 0.75 with emotional support) and boredom fell (d = -0.35, -0.67) only in the two scaffolded conditions. Plain

ChatGPT showed no significant change in either emotion. Hopelessness fell in every condition including plain ChatGPT (d = -0.73 to -1.02). Neither self-efficacy (η2 = 0.001) nor trust in the chatbot (η2 = 0.020) differed by condition, so the emotional design moved two emotions and left the motivational belief the theory predicted untouched (Diordiev, Stenberdt & Makransky, 2026).

Institutional support works on anxiety through appraisals, not reassurance. A two-wave survey of 547 Chinese undergraduates (Jiang, Chen & Chen, 2026) traced how perceived school support relates to AI learning anxiety through control-value appraisals — the learner's sense of competence (control) and of the tool's usefulness (value). Support predicted lower anxiety directly, but most of its association ran through the appraisals rather than around them: via AI learning self-efficacy, via perceived usefulness, and via a sequential route in which self-efficacy fed usefulness, which in turn lowered anxiety. A first-order model showed the support *dimensions* were not independently doing the work — only informational support retained a significant path to self-efficacy — and an artificial neural network cross-validation ranked self-efficacy and perceived usefulness as the most stable predictors of anxiety. The implication is that institutional encouragement aimed at anxiety only lands if it changes what students believe about their own capability and the tool's usefulness; general reassurance does not alter the appraisals that generate the anxiety.

AI can also relieve academic anxiety by advancing learning goals rather than by reassurance: across a survey of 721 medical students and an experiment with 398, higher perceived assistant capability predicted greater study-goal progress, which predicted lower academic anxiety and better mental health (Chen et al. (2026)).

Competence is not a full buffer, though: among 551 Chinese first-year students, self-reported AI usage pressure weakened the link between AI proficiency and psychological adjustment, with the AI-proficiency-to-adjustment slope falling from 0.42 under low pressure to 0.20 under high pressure (Zhang & Yin (2026)).

The route from competence to anxiety runs through ethics, and it can amplify. Among 584 undergraduates at a law-dominant Chinese university with no AI literacy curriculum, AI competence did not reduce AI anxiety directly (β = 0.056, p = .362). It raised AI ethical awareness (β = 0.644, p < .001), which in turn raised anxiety (β = 0.439, p < .001) — indirect-only mediation through a path the authors had hypothesized as protective (Mu et al. (2026)). Only 22.8% of anxiety variance was explained. An ANN on the same constructs ranked transparency first among predictors for both learning and job-replacement anxiety. **Faculty forecasts as a distributed form of AI anxiety.** Watson & Rainie (2026)'s survey of 1,057 US college and university faculty registers educator anxiety as expectations rather than symptoms: 95% expected generative AI to increase students' over-reliance on the tools, 94% more academic integrity concerns, 90% diminished critical thinking, 83% shorter attention spans and 81% wider digital inequities, while 39% believed the tools would diminish the role of faculty and 47% feared the long-term employment impact in their disciplines would be negative. The same respondents were not uniformly pessimistic — 61% still expected improved and customized learning — but 73% had personally dealt with an academic integrity case involving students' generative AI use, which is where a forecast turns into workload. The report is explicitly a non-scientific sample that is not generalizable, so it documents the sector's expressed fears rather than measured effects.

This direction connects AI anxiety to Motivation, AI Literacy, Student Experience, and Self-Regulated Learning.

An agent that resembles an examiner can carry an examination's pressure with it. Students who practiced speaking with Replika scored significantly higher than they did with peers, yet described the interaction as anxious and awkward and did not want to use it again — measured performance and experienced stress moving in opposite directions (Soriano-Gonzalez & Belda-Medina (2026)).

Career-related AI anxiety

A distinct and increasingly studied dimension is **career anxiety** — the fear that AI will displace jobs, erode employability, or devalue one's professional future. Where proctoring anxiety is situational and learner-emotion anxiety is about in-task competence, career anxiety is forward-looking and identity-level, and it is tightly linked to Career Development and Readiness. The AI Anxiety comprehensive analysis identifies the **fear of replacement by AI** as the primary contributor to AI anxiety, alongside uncontrolled AI growth, privacy, misinformation, and bias. A growing empirical literature now quantifies how this fear affects students:

- **Career adaptability is a protective factor.** Wang (2026) shows career adapt-abilities significantly and negatively predict AI anxiety among English majors, with core self-evaluations partially mediating the relationship; the low-adaptability group had the highest AI anxiety.
- **Threat and favorable appraisal co-activated in one profile.** Song et al. (2026) found a group above the sample mean on all six indicators at once — AI use anxiety 1.521 and STARA awareness 0.951 alongside perceived quality 1.753 — so high anxiety did not signal a negative appraisal of the technology.
- **AI anxiety impairs career decisions.** Duan et al. use structural equation modeling to show AI anxiety directly and negatively predicts career decisions, and does so largely by undermining **career adaptability** (accounting for 63.35% of the total effect); Self-Efficacy offered only limited buffering.
- **Growth mindset bounds the threat-to-employability path.** Among 526 Chinese undergraduates, AI employment-threat perception predicted higher career decision-making anxiety partly by lowering perceived employability, and the threat-to-employability link held only at low growth mindset ($b = -0.229$) and not at high ($b = -0.013$) (Chen (2026)).
- **AI anxiety predicts job-search anxiety at scale.** Üstün & Danacıoğlu (1,057 students) and Dağ et al. (821 health-sciences students) find AI anxiety and negative AI attitudes predict job-finding/job-search anxiety, with women, social-science majors, and lower-income students most affected.

Practical implication: building career readiness — adaptability, core self-evaluations, and employer-valued AI skills — is a validated intervention for reducing career-related AI anxiety, more than generic self-efficacy alone. Institutions should universalize AI Literacy and career-planning support, and address the equity patterning of career anxiety.

AI for detecting and relieving stress and anxiety

The positive side: AI systems increasingly detect and help alleviate stress and anxiety. - AI campus well-being tools span prevention (improved feedback collection) and intervention (advancing mental-health

detection). - Affective text + wearable sensing (a year-long study of 458 students with Oura rings) shows ultra-brief naturalistic text can complement wearable physiological sensing for longitudinal student health monitoring — a concrete AI-enabled stress-detection pathway. - This links to Affective Computing and Affective Tutoring, where AI reads and responds to emotional state. - **Which stressors the model weighs — and why context matters.** Bashir and Afzal (2026) offer a Machine Learning window on which stressors actually drive student distress in a non-Western context. Feature-importance analysis on 1,100 survey responses put blood pressure first (15.6%) and **teacher-student relationship second (10.0%)** — ahead of sleep quality (9.3%), depression (8.3%) and social support (7.6%) — while anxiety level ranked ninth at 4.8%, which the authors read as evidence that student stress is multi-dimensional rather than driven by a single psychological indicator. They attribute the salience of the teacher-student relationship to the comparatively hierarchical educational environment in Pakistan and present it as a hypothesis for locally collected data, underlining that stress models and their feature weights are context-dependent and cannot be assumed to transfer across student populations. - **Instructor-side real-time intervention.** Parlant's practitioner guide adds a human counterpart to these AI tools: *emotional micro-interventions* — brief, deliberate verbal or gestural acts that validate a student's emergent emotion, reframe the appraisal behind it, and reconnect the struggle to professional identity (Validate, Reframe, Connect). Grounded in cognitive appraisal theory, the approach targets the primary appraisal ("is this a threat?") and the secondary appraisal ("can I cope?") at the moment distress would end engagement, pairing bottlenecks such as frustration, isolation and imposter syndrome with target states. Its author states plainly that the framework does not require AI; generative AI serves only as an optional way to draft candidate phrases for the instructor to curate.

Why this is distinct from well-being

Well-Being is the broad positive state (emotional, psychological, social health) that AI can support or undermine. **AI anxiety and stress** is the specific, measurable emotion-construct within that space — it names the discrete negative affect and its productive uses, and it has its own dedicated evidence base (proctoring stress, productive AI anxiety, AI-driven stress detection). Rather than rivaling well-being, this page develops the anxiety/stress dimension in depth and cross-links heavily to Well-Being, Social-Emotional Learning, Affective Computing, and Remote Proctoring.

Practical guidance

- **Design for anxiety, not just integrity.** Proctoring and AI-monitoring systems should minimize false accusations and surveillance stress, especially for novice and vulnerable students; pair monitoring with accessible alternatives and clear communication.
- **Leverage productive anxiety.** Rather than only reducing AI anxiety, support the verification, revision, and self-AI Regulation in Education that anxious-but-engaged students already exhibit.
- **Use AI to detect and relieve stress** — via affective computing, wearables, and campus well-being tools — while guarding privacy.
- **Consider educator anxiety** in AI adoption and policy, not just student experience.

Common Misconceptions

- **“AI anxiety is purely harmful.”** This anxiety is **not purely negative**: Kim (2026) finds **AI anxiety can be productive**, with higher anxiety associated with more strategic regulation. Anxiety functions as a signal to scrutinize rather than only as a burden.
- **“All anxious students respond the same way.”** Kim’s **four regulatory types — Uncritical Reliance 18.7%, Selective Integration 34.6%, Evaluative Transformation 31.8%, Strategic Rejection 14.9%** — show anxiety-driven scrutiny producing **four distinct** patterns. An intervention targeting “anxious students” misses that the largest single group is selectively integrating.
- **“Anxiety always suppresses participation.”** That reframing has a **boundary in speaking**: among **708 English learners**, the speaking-anxiety to willingness link ran **-0.371 at low speaking self-efficacy but +0.137 at high**. Anxiety can accompany willingness when self-efficacy is high, so the effect direction depends on confidence.

Connected Concepts

Student Experience

> **Student experience** — how learners perceive, interact with, and are affected by AI tools in educational settings. With over 85 articles in the knowledge base, student experience is one of the most-researched dimensions of AI in education. AI impacts students in both positive and negative directions, and the same tool can help and harm depending on how it is designed and used.

Questions to Consider

- The page claims AI affects students in both positive and negative directions, often simultaneously — the same tool can help and harm depending on design and use. Can you give an example from your own experience where AI helped and hurt at the same time?
- It describes a 'performance-learning gap': students do better with AI but worse on later unassisted tasks. How do you think that gap arises, and what would it take to close it?
- If over-reliance on AI means delegating the reasoning you actually need to practice, where would you draw the line between legitimate help and offloading that erodes learning?
- The research asks whether simply knowing AI is available changes student effort. Do you think awareness of AI makes students work harder, less hard, or differently — and how would you test your belief?
- Given that AI access and effectiveness vary across student populations, what equity concerns do you think matter most when a course adopts an AI tool, and who is responsible for addressing them?

Introduction

How student experience is studied

- **Large-scale surveys:** AI in the Wild analyzes authentic interactions of thousands of college students, while availability and satisfaction studies correlate AI access with student outcomes. These are self-report measures: they capture perceptions and intentions well and behavior only approximately.
- **Non-use is a reasoned position, not a gap to close.** A cross-institutional UK survey of 7,087 students found 32% did not use GenAI for study at all, with non-users citing wanting to do the work themselves (86%), inaccuracy (81%), and ethical or environmental concerns (Gow et al., 2026).
- **Interaction patterns:** Tracing GenAI literacy maps how students engage with AI across assignments. Prompting analysis reveals cognitive engagement levels through prompt structure.
- **Motivation and agency:** AI availability and motivation examines whether knowing AI is available changes student effort. AIED's unfinished mission frames Learner Agency and Motivation as central challenges.

- **Perceptions and attitudes:** GenAI usage surveys and mental model studies investigate how students understand and trust AI.
- **Equity dimensions:** student-experience intersects with Equity — AI access and effectiveness vary across student populations.

Ways AI impacts students

AI affects students across cognitive, motivational, affective, identity, social, and equity dimensions. The research points to **positive and negative impacts in each dimension**, often simultaneously — the direction depends on design and use.

Cognitive impacts

- **Positive:** AI can scaffold learning with Feedback, hints, and explanations, supporting understanding, practice, and Help-Seeking. Students can use AI to learn how to use AI well, and well-designed tools keep the learner doing the cognitive work (see Does AI help students learn?).
- **Negative:** AI can drive over-reliance and cognitive offloading, where students delegate the reasoning they need to practice. This is the **performance–learning gap**: students do better *with* AI but worse on later unassisted tasks (see AI Misuse and Learning Harm). Overuse may also erode Metacognition and Self-Regulated Learning.

Motivational impacts

- **Positive:** AI can raise Motivation and engagement by providing personalized, immediate, and low-stakes support — helping students persist and feel competent (see self-determination perspectives on autonomy, competence, and relatedness).
- **The motivational effect runs through motivation, not through access.** Among 297 students, autonomy support and autonomous motivation for AI use had no direct effect on engagement ($\beta = 0.070$ each), while student motivation predicted engagement at $\beta = 0.74$ (Ahmed and Sultan (2026)).
- **Negative:** Knowing AI is available can reduce student effort and motivation to struggle productively (AI availability and motivation, the safety gap). Over-reliance can erode Learner Agency and the sense of accomplishment that comes from doing work oneself.

Affective and well-being impacts

- **Positive:** AI can offer low-pressure, on-demand help and reduce anxiety about asking questions, supporting Well-Being and confidence.
- **Negative:** AI use is associated with anxiety and stress, including fears about being replaced, uncertain assessment, and the pressure to keep up. Studies such as a comprehensive analysis of AI anxiety and AIvaluate document these affective costs. Shame and guilt around AI use can drive hiding and selective disclosure, harming honest engagement and social-emotional well-being. These pressures are local and social rather than written down: see social norms of AI use. Assessment conditions add their own pressure: a scoping review of remote proctoring in nursing

assessment finds students anxious about connectivity and about being wrongly accused of cheating, first-time users of an invigilation app describing it as anxiety-inducing and reporting difficulty concentrating while watched, and roughly a fifth hitting browser-extension or connectivity failures despite preparatory resources.

Identity impacts

- **Positive:** AI can support identity formation by scaffolding disciplinary belonging, confidence, and professional aspirations — e.g., helping students see themselves as capable practitioners.
- **Negative:** AI can threaten learner identity through authorship loss and competence doubt — when AI produces the work, students may stop feeling it is "theirs." The competence paradox in creative fields shows ease-of-use undermining the craft-based identity students derive from authorship.

Academic-integrity and fairness impacts

- **Negative:** AI enables new forms of academic dishonesty (AI-generated essays, unauthorized completion), driving debates about detection and reduction. This interacts with equity: unequal access to, and understanding of, AI tools can widen gaps between students.
- **Whether a use counts as cheating depends on the discipline.** A systematic review of 89 studies found STEM students at +42% net agreement that AI improves performance, while humanities students showed the highest net agreement that AI use constitutes cheating (+44%) and raises ethical concerns (+58%) (Padhy (2026)). A course's integrity problem is therefore partly a disciplinary judgment rather than a fixed standard, which is why the rules students encounter vary by department as much as by policy.
- **Positive/constructive:** AI can support authentic, process-oriented assessment and reflective practice (e.g., guided self-assessment), turning integrity concerns into opportunities for AI Literacy and responsibility.

Student accounts of integrity are less settled than the dishonesty framing suggests. Mulisa and Mezgebu (2026) interviewed 27 undergraduates at an Ethiopian university and found the student body divided against itself: almost all used GenAI or watched peers use it and most credited it with raising their achievement. A minority called coursework use outright misconduct, and the sharpest and most widely shared complaint was fairness — AI users scoring above students who worked honestly. That left some describing it as killing their sense of diligence, and one participant unsure "whether we are benefiting or suffering from the use of AI." The procedure side matters too: Munoz et al. (2026) coded 1,162 GenAI misconduct cases and found that the evidence most often cited — detector output, similarity reports, AI-typical content patterns — carried the weakest probative value, and that with no minimum evidentiary threshold in the pipeline students with thin cases were pushed toward appeals. Over-inclusive definitions broaden that exposure: Wright (2026) shows that prohibitions aimed at "generative AI" can catch tools that merely convert the format of work a student already authored, an over-inclusion that falls hardest on disabled and equity-exposed students. Sharma (2026) points the constructive way out, treating integrity as a pedagogical practice enacted through judgment — annotated decision trails, verification, oral defense, version history — rather than compliance secured through surveillance.

Verification can shift how students experience the question: a request to explain their work first read as an accusation, but once the syllabus framed it in advance as pedagogy rather than surveillance they disclosed AI use more openly and treated assignments as learning tasks, in five-to-ten-minute conversations (Mandernach, 2026).

Social and relational impacts

- **Positive:** AI can mediate collaboration and human-AI interaction, supporting teamwork, peer interaction, and access to diverse perspectives.
- **Negative:** AI can reduce genuine peer and instructor interaction, create sycophantic dynamics, and — when operating as an undisclosed teammate — reshape group discourse and Learner Agency in ways learners cannot see or contest (see emergent learner agency in implicit HAI).

Long-run / capability impacts

- **Positive:** AI can help students build transferable skills for an AI-integrated workplace — adaptive capabilities such as AI Literacy, Distributed Cognition, and Metacognition — and raise expectations about AI-skills readiness (AI-skills expectations for graduates).
- **Negative:** An over-reliant or unreflective AI experience can leave students less able to perform without AI, less practiced at independent reasoning, and uncertain of their own capabilities (see AI misuse and learning harm).

Overall: the same AI tool can support or undermine students depending on design and use. The guardrail throughout is to keep the learner doing the cognitively important work while using AI for support (scaffold, do not substitute), and to attend to the full range of impacts — not just performance. One configuration shifts where the experience begins: when AI generates the course readings themselves rather than helping with homework, students become auditors of their own curriculum. In Sidorkin's (2026) graduate course, students valued the contextual specificity and adjustability of the generated texts and 75 percent agreed they learned more than in a comparable course without an AI companion, yet they had to infer source quality from context because Wikipedia links and peer-reviewed citations appeared in the same lists without labels, and four of 24 survey respondents used dependence language, including one describing themselves as "somewhat codependent on the AI for reassurance and structure."

The longest-run outcomes a student experiences — whether they return next term, accumulate credits, and graduate — are institutional rather than instructional, and Student Support and Success tracks how AI support affects them: task completion moves readily, persistence and graduation far less so.

Connections

Student experience connects to Over-Reliance (excessive AI dependence), AI Literacy (skills for effective use), Cognitive Offloading (how AI changes cognitive work), and engagement (how AI systems measure and respond to student behavior). It is the learner-facing member of the Stakeholders umbrella, and the home for summarizing all the ways AI impacts students.

Common Misconceptions

“Students who avoid AI are behind.” Non-use is frequently a reasoned position rather than a gap: a cross-institutional UK survey of **7,087 students** found **32% did not use GenAI for study at all**, with non-users citing wanting to do the work themselves. Treating that as an adoption deficit inverts the finding and pressures students out of a defensible choice.

“Student reports are a reasonable measure of learning.” They are self-report measures: they capture perceptions and intentions well and behavior only approximately. The performance–learning gap in this literature — students doing better with AI and worse on later unassisted tasks — is precisely the case where self-report and outcome diverge, so a satisfied student body is not evidence of a learning student body.

“If students feel AI helps, it helps.” Feeling helped is a real datum about the experience and an unreliable inference about the outcome. The gap is documented and students in the harmed group do not reliably perceive it, so perception and outcome have to be collected as separate measures rather than one standing in for the other.

“Student experience is a soft concern relative to outcomes.” It is a leading indicator for adoption and disclosure: students who feel their use is judged will conceal it, and concealed use is the condition in which misuse and harm are least visible to the institution.

Implications for Practice

For instructors

- Do not treat non-use as a gap to close. Roughly a third of students choose to do the work themselves, and pressure to adopt converts a reasoned position into a compliance problem.
- Collect perception and outcome separately. Satisfaction surveys describe the experience and cannot stand in for unassisted performance.
- Make disclosure safe, since students who expect judgment conceal their use, and concealed use is where the divergence between assisted and unassisted performance hides.

For developers

- Report learning outcomes alongside experience metrics in anything you publish to students, because the felt and measured results routinely diverge.
- Support declining the assistant without losing access to the course.

For researchers

- Report the size and reasons of the non-user group explicitly; 32% of a 7,087-student sample is a population, not a residual.

Student Support and Success

> **Student Support and Success** — the institutional-side work of helping students stay, progress, and finish: **advising, administrative assistance, outreach, referral, and the allocation of scarce support**. This is the page for what institutions *do to* students rather than what happens *inside* a course. Higher Education is the broader umbrella for the sector and Student Experience covers how AI lands on the student's own experience; Learning Gains measures whether learning happened. The distinctive finding in this knowledge base is that AI support reliably moves **task completion** — a dated, binary action a student controls and the institution can observe — while leaving **persistence, credits, and graduation** largely untouched. Separating those outcomes is the point of this page.

Questions to Consider

- Which outcome are you trying to move? A registration reminder and a retention program are different interventions with different evidence, and the research here suggests one does not buy the other.
- If a model flags a student as at risk, what happens next? Who acts, with what capacity, and what would make the recommendation feasible rather than merely accurate?
- Support capacity is finite. When AI ranks or allocates it, what does that do to the students a human advisor would have noticed anyway?
- Who is accountable when an automated message, referral, or risk score is wrong? The student sees the consequence; the institution owns the system.
- Does your support data travel? Cross-office sharing is what makes targeting possible and is also the most common reason targeting quietly stops.

Introduction

Student support sits on the institutional side of the relationship. Its work is advising, outreach, referral, and the allocation of finite human and financial capacity; its evidence base is administrative records, registration events, credits earned, and whether a student returns. Generative AI entered this territory later than it entered instruction, and much of the literature here concerns **non-generative** systems — text-message chatbots, early warning models, federated risk prediction — with generative tools arriving as advisors, assistants, and knowledge-base responders.

The distinction that organizes this page is between **what a nudge can do** and **what a trajectory requires**. Support technologies excel at a dated, binary decision: register by this date, complete this form, start Early Start. They have far more difficulty with cumulative outcomes — persistence, credits, graduation — which instruction, finances, employment, family circumstances, and prior preparation all shape. The knowledge base's strongest evidence on this comes from a four-year randomized evaluation that moved registration sharply and graduation not at all.

The support functions

The research clusters into five functions, and the cluster boundaries matter because they carry different evidence.

Outreach and communication. Institutions message students at scale, and the strongest evaluations test whether it changes anything. A four-year randomized study of CSUNny, a non-generative text-message chatbot at California State University, Northridge, followed two undergraduate cohorts (N = 8,708) through eight semesters (Mata, Russell & Page, 2026). A registration reminder sent July 31, 2018 made treated students 34 percentage points more likely to enroll by August 16 and only 2 points more likely by September 15; Early Start reminders produced 11 points more registration by June 7 and 20 points by June 22. Receptivity held: annual opt-out rates never exceeded 4%. A pre-registered multi-semester trial at Georgia State University nudged students in two large asynchronous courses (N = 1,568 and N = 915) with two to three customized messages a week, raising the odds of earning an A or B by four percentage points against 61% of controls and shifting DFW rates by about three points in each course (Meyer et al., 2026).

Advising and academic planning. Course and grade prediction supplies the planning input — one model jointly predicts which courses a student will take and the grades they will receive (Savala, 2026), and another predicts module-level progress in large online programming courses with an intrinsically interpretable decision tree (Zhang, Jeffries & Koprinska, 2026). Transfer credit is an advising problem in its own right: CourseGraph models course content as knowledge graphs to evaluate external course equivalences for mobile students (Nijdam et al., 2026). At the institutional level, a review of 155 studies of AI and service delivery in higher education found learning analytics the most common application at 46 studies (29.7%), ahead of chatbots and virtual assistants at 31 (20.0%) and predictive analytics at 29 (18.7%) (Nyamboga, 2026).

Referral and support allocation. Prediction is not a plan, and the gap between them is where the field's sharpest critique sits. SC2R formalizes it as the **actionability gap**: a risk score becomes decision support only when its recommendations are semantically feasible and machine-checkable — constrained by timing, budget, immutability, and availability rather than merely model-valid (Le, Abel & Laforge, 2026). Whether models can allocate support well is contested empirically: asked to recommend support plans for 4,500 synthetic student vignettes, three LLMs showed limited sensitivity to student need and sharp inconsistency across models (López-Pernas et al., 2026).

Academic support access. Course-specific retrieval systems aim at the students least likely to ask a human. Beacon, built from a single programming module's approved materials, drew high relevance ratings (89%) and was judged by most students to support rather than replace their learning (66.7%), in a small evaluation of 15 students and 4 academics (Zhou et al., 2026). Tutoring take-up is its own problem: a two-year randomized trial of a virtual tutoring layer for struggling students had to test take-up separately from learning, because reaching the students who need support is not the same as providing it (Fryer et al., 2026).

Administrative assistance. Leadership and administration are studied as their own application domain, with a ten-domain taxonomy mapping where AI lands in educational leadership (Sposato, 2025). Institution-run services reach past advising into health: an integrated campus well-being framework pairs prevention — improving how feedback is collected — with intervention through mental-health detection (Tang, 2026).

Credentialing sits adjacent: when an agent can complete a course on a student's behalf, a credential that says "earned" loses its meaning, which turns completion records into a design problem (Srivastava, 2026).

What an AI support channel displaces deserves the same accounting. Across four studies (N = 249, 494, 743 and 737), belief in AI's capacity to provide emotional support raised willingness to offload that support to it, and the effect travelled entirely through perceived capacity (total effect c = 0.83; indirect effect ab = 0.73) (Shastry & Gray, 2026). On a behavioral measure, participants who said they would not offload chose fewer empathy words, so routing students to an AI well-being channel can subtract human support in ways self-report does not show.

From prediction to support

Risk prediction — early warning systems, dropout models, at-risk classifiers — is **Learning Analytics** territory in this knowledge base, and this page treats *predictive analytics* as the same thing. The modeling work is substantial: supervised classifiers identify students before withdrawal from academic performance, demographic, and enrollment records (Gheisari & Salarian, 2026); a dual-layer framework combines Codeforces behavioral logs (n = 1,816) with psychographic survey data from ten universities to predict attrition in competitive programming (Alam et al., 2026); and a federated architecture predicts performance and dropout across institutions without sharing raw student data, reaching AUC = 0.918 on OULAD against 0.925 centralized (Villegas-Ch et al., 2026). A precision-education vision extends the logic to student digital twins and "preventive student success" (Han et al., 2026).

What belongs *here* is the step after the score: **support allocation**. Two findings set its limits. First, the ranking-versus-calibration split — federated risk models kept their AUC under distributional shift while their calibration degraded markedly, so a model that still ranks students correctly can be wrong about how likely each one is to need help. Second, the enabler study: an international Delphi and AHP/SNAP analysis of learning-analytics-to-intervention identified seven enablers and ranked **institutional strategic orientation** highest (priority 0.2072) and most influential on the others (PageRank 0.2430), locating the bottleneck in institutional planning rather than in the models (Svetec, Divjak & Kadoić, 2026). Behavioral clustering of 14,003 student records into six profiles, mapped to recommended learning objects, is the recommendation layer this points toward (Najem et al., 2026).

An integrity outcome joins the same pipeline. Akçapınar (2026) predicts AI-assisted cheating risk from early-semester LMS traces (AUC 0.763) and recommends acting on it only through low-stakes outreach, with the decision threshold chosen for reach rather than accusation: dropping it to 0.30 identified 21 of the 23 high-risk students, at a precision of 60%.

The outcome ladder: what each measure actually means

The word "success" hides at least five different measurements, and AI support does not move them equally. Distinguishing them is the most useful thing this page can do.

- **Task completion** is a single, dated, binary action the student controls and the institution observes within days — registering by a deadline, filing a form, enrolling in Early Start. It is where nudges work, and the effects can be large and immediate (34 percentage points, then 2, in the CSUN registration reminder).

- **Credits (units enrolled and earned)** are cumulative and depend on course availability, sequencing, and how many terms a student can afford. In the CSUN evaluation no significant treatment effect appeared on units enrolled, earned, or cumulatively earned.
- **Persistence** is continuation across terms — enrollment by semester sequence — and it did not move either, at N = 8,708 with power to detect effects of 0.05 standard deviations or larger.
- **Retention** is the institutional rate that persistence produces, and it is usually reported at the program or cohort level. Course-level DFW rates are the closest thing to a leading indicator in this literature, and they moved modestly (−3 percentage points in each course of the Georgia State trial).
- **Graduation** is the terminal, multi-year outcome. Control mean graduation by the fourth year was 0.190 in the CSUN study, and the treatment effect on it was not statistically significant.

The authors' explanation for the pattern is the page's central claim: a reminder acts on a decision that is discrete and near-term, while persistence and GPA are cumulative and shaped by instruction, finances, employment, family circumstances, and prior preparation. They conclude that communication through a tool like this, **on its own**, may be insufficient to change them — and that the nulls are precise rather than underpowered. Early registration still carries institutional value for staffing and space planning even where learning outcomes do not move.

Equity and the risks of acting on a score

Support systems act on students, which makes their failure modes different from a tutor's. A stress test of six post-hoc fairness interventions on a replicated vendor-controlled early warning system built from 168,550 student records found the interventions failing to deliver the fairness they promised (McConvey et al., 2026). A student-advocacy review organizes the risk surface around admissions, recruitment and financial aid, and **student-success services** — the areas where institutional AI bears most directly on students (Student Defense, 2026). Privacy and equity are structural here rather than incidental: federated learning exists because sharing student records across institutions is unacceptable, and the human-in-the-loop component in the CSUN program is what the authors argue reaches students who ignore email and phone. Administrators answer what the chatbot could not, then fold the answer back into its knowledge base.

The institutional conditions

Durability in this literature is an organizational property, not a technical one. The CSUN program survived four years because the channel was centrally owned, jointly overseen by the Office of Undergraduate Studies and the Office of the Registrar, and written by a single communication specialist for a consistent voice. Its targeting decayed for an equally organizational reason: because student data was not centralized, a financial-aid reminder required one office to identify non-filers and another to pass the subset along, and that friction was burdensome enough that targeted campaigns fell from 36% of all campaigns in AY2018-19 to 6% by AY2022-23. Where the work sits, who owns the data, and whether cross-unit coordination is sustainable decide what a support system can actually do — which is why this page carries Change Management, AI Governance, and Educational AI Policy as facets rather than treating deployment as an IT decision.

Connections to related concepts

Student support connects to Student Experience as the student-facing counterpart — the same technologies seen from the student's side rather than the institution's — and to Help-Seeking for the mechanism by which students who need support actually obtain it; outreach and course-specific assistants are both attempts to lower the cost of asking. Learning Analytics owns the prediction that feeds allocation, Learner Modeling and Adaptive Instruction and Knowledge Tracing the models underneath it, and Recommender Systems and Learning Paths the recommendation layer. It connects to Well-Being through campus mental-health and prevention systems, to Career Development and Readiness as the outcome that follows completion, to Equity and Privacy through the risks of acting on scores, and to Administrators, Stakeholders, and Change Management as the roles and processes that decide whether any of it is sustained. Learning Gains is the adjacent measurement node: this page's outcomes are administrative rather than instructional, and the two do not move together.

Common Misconceptions

"Predicting which students will struggle is the intervention." Prediction is the input to support and is not support. The corpus separates these deliberately: a registration reminder and a retention program are different interventions with different evidence, and the research suggests one does not buy the other. An early-warning dashboard that ends in a score has added measurement without adding help.

"A retention programme that raised persistence proves the AI worked." It proves the program did, and the AI layer must be evaluated separately from the outreach it triggers. A four-year randomized study of CSUNny, a non-generative text-message chatbot at California State University, Northridge, followed **two undergraduate cohorts (N = 8,708)** through **eight semesters** with **annual opt-out rates never exceeding 4%** — a strong receptivity result about *messaging*, and not evidence that a generative or predictive system would achieve the same.

"The outcome ladder collapses: engagement is retention." Each rung measures something different — opting in, responding, persisting, completing — and a program can move the lower rungs while leaving the upper ones flat. Reporting the responsive share as a success commits precisely that substitution.

"An equity concern is a reason to stop using the data." It is a reason to act on scores carefully. Acting on a predictor can distribute support and can distribute suspicion, and the risk concentrates on the students the model classifies least favorably — which makes the remedy governance of the use, not abandonment of the measurement.

- How Can AI Agents Support Students and Instructors?
- How Do We Write and Implement an Institutional AI Policy?

Social Norms of AI Use

> **Social norms of AI use** — the informal, locally enforced rules that decide when learners and instructors may use generative AI, how openly they can admit to it, and what counts as cheating in practice rather than in policy. The corpus is thin on norms as a topic and thick on the mechanisms that produce them. Learners cannot reliably infer each other's AI use: the median correlation between a perceiver's estimates and their own self-reported usage profile was r = .73 at both waves, and rank accuracy for the *kind* of AI use was r = .34 at the second wave. Shame and guilt regulate visibility rather than use, producing hiding and selective disclosure instead of behavior change. Disciplinary norms diverge sharply: AI-integrated assignments appeared in 27% of business syllabi and 5% of humanities syllabi across 31,000 courses. And the formal Ethics literature routes the fewest and least actionable norms to end users, meaning the people subject to classroom norms are largely absent from the documents that discuss them.

Questions to Consider

- If students cannot tell who is using AI, what are the informal rules actually based on?
- Where do AI norms come from when an institution has no policy, or when the policy contradicts what instructors say in class?
- Why would a student who has never used AI report more guilt about it than a student who uses it weekly?
- What does shame accomplish that a policy cannot, and at what cost to asking for help?
- Does surveillance change behavior, or only how visible that behavior is?
- Whose norms dominate in a group assignment, and who absorbs the cost of the group's shared AI habits?
- Should students have a hand in writing the norms they are held to?

Introduction

Formal AI Regulation in Education of AI in education arrives as policy: acceptable-use statements, syllabi clauses, detection procedures, proctoring systems, honor codes. Everything students actually experience, though, sits underneath that layer. A classmate who never mentions using ChatGPT, an instructor who says "I don't care how you write it" and then bans it in the syllabus, a study group that has quietly settled on what is fair, a department where everyone assumes the grading curve has already shifted. These are norms: shared expectations about acceptable behavior, enforced by approval, disapproval, and the risk of being seen.

This page collects what the evidence base says about that layer. It is worth separating carefully, because "hidden curriculum" is often used loosely to mean anything unofficial. Here the subject is narrower: the operative rules about AI use, how they form, how they are enforced, and how weak the connection is between them and the written rules. The corpus has almost no study that measures norms directly, which is

itself a finding. What it has is repeated evidence about the mechanisms: inference, disclosure, emotion, and the disciplinary variation that shapes what any local norm can become.

What students believe about each other

Norms require information about other people's behavior, and that information is worse than most instructors assume. A study of student pairs tracked how accurately learners judged a partner's AI use across pair-programming sessions. Against each partner's own self-reported usage profile, the median correlation was r = .73 at both waves, high enough to feel like knowledge and low enough that many individual estimates were wrong. Rank accuracy for the type of AI use was r = .34 at the second wave, and 25% of teams became worse at judging their teammates over time.

Two details matter for norms. First, misalignment did not shrink with repeated face-to-face work. Familiarity did not produce accuracy, which undermines the assumption that norms stabilize as groups get to know each other. Second, the authors' proposed fix was structural rather than attitudinal: shared prompt histories, AI-use annotations, or peer-visible records of AI-supported work. Making AI use visible is a different project from making students more honest or more perceptive about it, and only the first one has evidence behind it.

Visibility, shame, and selective disclosure

If peers cannot see AI use accurately, then the rules that develop around it are enforced largely through social risk. An interview study with 19 computing students examined shame and guilt as social regulators and found that they govern disclosure rather than use. Students described hiding behaviors and selective disclosure, and they reported shaming themselves, their peers, and their faculty. The important negative result is that these emotions coexisted with continued AI use, generating cycles of reduced Learner Agency and moral tension rather than prompting anyone to stop.

That pattern relocates the norm from "use or don't use" to "admit or don't admit." A classroom can have a strong anti-AI norm on paper, widespread use in practice, and an equilibrium of silence in between, without anyone being confused about what the rule says. It also predicts where the cost lands: on learners who are least able to manage the social risk, and on learners whose visible use carries different consequences.

The instructor side of the same emotion is measurable. A survey of faculty using a four-item AI Guilt Index (Cronbach's alpha = 0.88) found anticipatory guilt exceeding experienced remorse: the mean index score was 2.39 (SD = 1.01), with 22.9% of participants above the midpoint. Non-users of AI reported *higher* guilt (M = 3.25, SD = 1.04, n = 8) than users (n = 101, M = 2.32, SD = 0.97), t(8.39) = 2.00, p = .078, and the remorse item separated the groups more sharply, t(7.79) = 2.44, p = .041. Cluster analysis produced four profiles: Comfortable Adopters (26.6%), Guilty Non-Users (29.4%), Cautious Users (28.4%) and Morally Distressed Avoiders (15.6%), with differences confirmed on guilt, F(3, 105) = 22.13, p < .001, eta-squared = 0.39.

A norm that makes people who have not acted feel guilty is doing its work through anticipation. That is a real regulatory mechanism, and it is invisible to any policy audit that looks only at what faculty and students do.

A survey of 409 undergraduates puts the same mechanism into a regression: perceived peer disclosure and comfort with instructors were the strongest predictors of a student's own disclosure, ahead of moral

disengagement (Qu and Wang (2026)). What a student treats as the norm is what they believe their peers do, which is the impression the perception study above shows to be systematically coarse. Disclosure, on this evidence, is a response to a believed norm rather than to a written rule or to a personal ethical standard.

The local rulebook: disciplines and classrooms

Norms are local, and the evidence on how local is unusually concrete. An analysis of 31,000 course syllabi found that AI-integrated assignments ranged from 27% in business to 5% in the humanities. The range is not a gap in policy compliance; it reflects different disciplinary judgments about what the work is, what practice is worth, and which skills a credential is supposed to certify. The authors' recommendation follows from that: grant instructors autonomy within disciplinary norms rather than issuing one-size-fits-all mandates, because the mandate would have to be written for an average that does not exist.

The classroom layer can also contradict the document layer in the same course. Interviews with marketing students found peer norms and "keeping up" driving adoption, with word of mouth described as the biggest promotion AI has, sustained by fear of falling behind. The same study recorded a contradiction that instructors will recognize: some classes required AI while the syllabus banned it, and an instructor's in-class encouragement did not always survive into the written policy. When those two disagree, students treat the spoken norm as the operative one, and the syllabus as a liability to be managed.

Group work is where informal norms do the most work, because the unit being graded is collective. A study of 52 pre-service teachers across 15 focus groups identified distinct patterns rather than one enthusiasm-to-avoidance line, with groups negotiating what counted as legitimate assistance in the absence of a shared rule. Any student who has watched a group quietly settle on one member's AI use has seen a norm being written in real time, without a policy process and usually without a record.

Formal ethics, lived norms

The professional literature on AI ethics and the classroom norm it is supposed to reach are drifting apart, and the gap is documented. A systematic review of ethical values and norms extracted norms from 15 articles and mapped them onto four stakeholder sets from Smuha (2022). Developers received the most norms, followed by educational institutes and regulators. End users received the fewest and the least actionable, with no norms addressing students directly on non-discrimination, data stewardship, or educational aptness, and student voices essentially absent from the material.

The result is a literature that specifies obligations for the people building and procuring AI, and leaves the people living with it in the classroom to work out their own rules. That is a plausible explanation for why the norms students describe, as in the shame and guilt study, are so often about visibility and reputation rather than about the values the ethics documents name. The two systems are regulating different things.

Why surveillance does not settle norms

When institutions try to replace informal norms with formal monitoring, the evidence is consistent and unflattering. A four-wave study of 1,760 students across 105 courses found that online proctoring significantly increased test anxiety, and had no effect on the temptation to cheat. It also did not change

perceived difficulty or exam performance. The anxiety cost was concentrated among already-vulnerable students, including those with weaker home environments and less reliable technology.

Two further studies explain why surveillance is a poor tool for norm-setting. A scoping review of remote proctoring found that monitoring was widely perceived as deterring misconduct, yet South African lecturers reported continued dishonesty despite active monitoring, a situation Khalil et al. (2022) call "subterranean ethics," and frequent minor alerts generated false positives and faculty review work. Surveillance buys compliance through fear of detection rather than commitment to a shared standard. A model of assessment under imperfect information sharpens the mechanism: deterrence depends on a detector's ability to discriminate between hidden use and legitimate work rather than on its catch rate, and when false positives rise faster than true positives, students disengage from the system instead of complying with it. Its further result is the one that bears directly on norms: monitoring lowers the attractiveness of hidden use, but it does not increase disclosure. Students move toward openness only when reporting is safer or more valuable than concealment, and a prohibition can make concealment more attractive than compliance.

The procedural-justice argument draws the conclusion: because skilled or lightly edited AI use is undetectable in the general case, a misconduct procedure built on detection produces unfairness without effectiveness, and the answer is better Assessment, not better surveillance.

The cost of that substitution shows up in where faculty and students actually talk. Across 253,222 AI-related records from 26 education subreddits, a third of all faculty–student threads were detection or enforcement disputes, students opened 68.4% of them, and negativity predicted engagement ($\rho = -0.72$) — adversarial conflict, not deliberation, is the highest-volume form of cross-role contact about GenAI (Yüce et al. (2026)).

What this means for practice

- **Make use visible instead of inferring it.** Students cannot judge each other accurately, and repeated collaboration does not fix it. Lightweight shared records of AI-supported work, annotations, or prompt histories give a group something factual to reason about.
- **Expect the spoken norm to beat the written one.** If what is said in class contradicts the syllabus, students will follow the classroom. Alignment between the two is worth more than a stricter clause.
- **Treat disclosure as a design problem, not a virtue problem.** Disclosure becomes likely when reporting is safer or more valuable than hiding. That means making disclosed use legible in the assessment itself, rather than asking for honesty as a character trait.
- **Respect disciplinary variation.** A 27% to 5% spread across departments is not inconsistency to be normalized away, it is different judgments about what the credential certifies. Institution-wide mandates tend to be written for a discipline that does not exist.
- **Do not reach for monitoring to set norms.** Proctoring raised anxiety without changing the temptation to cheat in the strongest study available, and it concentrates that cost on the least advantaged students.
- **Ask who is missing from the norm.** The ethics literature assigns students almost no obligations and takes little account of their judgment, while the classroom assigns them a great deal and enforces it socially. Closing that gap is a curriculum question, not a compliance question.

Common Misconceptions

“Students know how much their peers use AI.” They overestimate their own knowledge of it. The median correlation between a perceiver’s estimates and their own self-reported usage profile was **r = .73 at both waves**, while rank accuracy for the *kind* of AI use was only **r = .34**. Students can tell roughly how much, and cannot tell what kind — which means norms form around an impression that is systematically coarse.

“Publishing a policy establishes the norm.” The local rulebook is written in practice, not in policy text, and domains diverge sharply: AI-integrated assignments appeared in **27% of business syllabi and 5% of humanities syllabi** across **31,000 courses**. A student’s operative norm is their own discipline’s, and an institution-wide document does not overrule it.

“Shame and guilt discourage AI use.” They regulate visibility rather than use: shame and guilt regulate visibility, producing hiding and selective disclosure instead of behavior change. The observable effect of a shaming norm is less honest reporting, not less use.

“Surveillance would settle the norm by making use visible.” Making behavior visible does not resolve what the norm should be; it changes what people are willing to disclose. The measured pattern is selective disclosure already, so a monitoring regime applied to it measures the concealment rather than the conduct.

“Norms are informal, so they are outside institutional reach.” They are locally enforced and locally changeable, which makes them more tractable than policy: a course team’s explicit practice is a lever precisely because it is where the operative rule is set.

Lifelong and professional learning

Career Development and Readiness

> **Career development and readiness** — the processes and capacities that prepare learners to build, adapt, and sustain a career in an AI-disrupted labor market: career adaptability, employability, workforce readiness, and the skills (including AI Literacy) that employers value. In the AI-in-education context this concept is increasingly important because AI both reshapes the skills graduates need and generates **career-related AI anxiety** about job displacement — making career readiness a protective factor for student Well-Being.

Questions to Consider

- Career readiness here is framed as adaptability — the capacity to navigate, adjust, and thrive across changing roles — rather than just credentialing. How does that reframing change what you think a career-focused education should actually build?
- Research consistently shows career adapt-abilities significantly reduce AI anxiety about job displacement. Why might being more adaptable to career change make a student feel less anxious about a technology that threatens their current job prospects?
- One key claim is that AI literacy on its own does not make a graduate career-ready, because readiness also runs through what students believe they can adapt to. Can you think of someone who is highly AI-literate yet still anxious or unprepared for the workforce? What were they missing?
- An ITHAKA S+R report documents a skills-prioritization gap: instructors emphasize critical, responsible use of AI, while employers favor workflow automation and human-AI teaming skills — and they agree on only one of 26 AI skills. Why do you think classroom and workplace priorities diverge so sharply, and who should adapt?
- The report finds most institutions lack both a consensus on what AI skills look like and an assessment framework for them. If you had to define and assess ‘workforce-ready AI skills’ for a graduating student, what would you measure and how?
- Fear of replacement by AI is identified as a primary driver of AI anxiety, and career readiness is positioned as a protective factor for student well-being. How should an education program address the anxiety itself, rather than only adding skills?

Introduction

As AI transforms occupations, education’s role in career development has broadened from credentialing toward building **adaptability** — the capacity to navigate, adjust, and thrive across changing roles. This concept connects education to employability and links to Anxiety and Stress: students with stronger career adapt-abilities experience less AI anxiety.

How career development and readiness appears in the knowledge base

- **Career adaptability reduces AI anxiety.** Wang (2026) shows career adapt-abilities significantly and negatively predict AI anxiety among English majors, with core self-evaluations partially mediating the relationship; the low-adaptability group showed the highest AI anxiety. Duan et al. confirm the mechanism with SEM: AI anxiety impairs career decisions largely through eroded career adaptability (63.35% of the total effect), and self-efficacy offered limited buffering. Üstün & Danacıoğlu add that AI anxiety and negative AI attitudes predict post-graduation job-finding anxiety across 1,057 students, with women, social-science majors, and second-years most affected. Dağ et al. extend this to health-sciences students (821, r = 0.233). Career readiness is thus an empirically validated buffer against career-related AI anxiety.
- **Readiness tracked engagement, not threat level.** In Song et al. (2026), the most AI-anxious profile still reported the highest career crafting (4.222) and self-perceived employability (3.964), alongside the favorable profile that did not differ significantly — so anxiety level did not index career readiness.
- **AI literacy is necessary but not sufficient.** Testa et al. argue AI literacy alone is not enough for career readiness — students also need adaptability and positive self-evaluations, directly linking AI Literacy to career outcomes. Hendrawan and Lestari (2026) test it quantitatively with 455 final-year students in Jakarta: career adaptability carries a significant indirect effect (β = 0.173), and growth mindset does not moderate the path at all, so adaptability rather than mindset does the work.
- **The mediating belief is a concrete future self.** In a survey of 1,945 Chinese university students, AI literacy's association with perceived employability ran through future work self salience (0.503 to 0.201, indirect 0.117) more than three times as strongly as through boundaryless career mindset (0.034) (Qiu et al., 2026).
- **A construct map, not a measured pathway.** Kong and Zhang (2026) read 46 publications as a critical narrative review and place three learning processes between AI-supported learning and employability: cognitive engagement with self-regulation, self-efficacy with motivational regulation, and career adaptability as the bridge to career exploration. They classify career adaptability as a career-development resource, not an employment outcome. Because the synthesis collects no data of its own, it offers testable propositions rather than an effect size, and every figure it reports belongs to an included study. A twelve-week UK module with 120 non-STEM students, for instance, associated AI capital with employment status six months after graduation, which a non-randomized single-course design cannot attribute to the course.
- **Employer and graduate perspectives.** The ITHAKA S+R report (500 US four-year-college instructors, compared against 200 US employers) documents a **systematic skills-prioritization gap** between instructors and employers that signals the workforce demands shaping higher education curricula. Instructors and employers agree on the importance of only one of 26 AI skills (setting realistic expectations for AI-augmented work): instructors prioritize a *critical, responsible-use* orientation (attribution, human accountability, limits of AI), while employers favor *workflow, automation, and human–AI teaming* skills. The report finds only three of 26 skills

are taught by half or more instructors — the under-taught categories (workflow redesign, automation, technical integration) are precisely where employer demands diverge most — and that most institutions lack both a consensus on what AI skills look like and an assessment framework for them. For career development, this means graduates' readiness depends on closing a real, measurable gap between what employers value and what curricula teach, not just on adding AI literacy.

- **Employers respond to the signal, not only to the skill list.** Boyd-Swan and Reynolds (2026) randomized about 1,750 US hiring professionals across two framings of student AI use before they rated otherwise similar resumes. Framing AI as an assistive tool raised concern only modestly and did not penalize applicants; framing it as a substitute for student effort and ability lowered interview likelihood and, more sharply, willingness to negotiate salary, with high-GPA applicants taking the larger penalties. Both treatment groups named in-person testing as the remedy that reassured them, which makes readiness depend on whether a credential still carries evidence employers will accept.
- **AI-free hiring screens stop certifying what the work requires.** In interviews with 23 Indian engineering students and recent graduates, all but one used AI to prepare for placement screens that excluded it while graduates described workplaces that expected AI from the first day, so on signaling theory a CGPA produced with AI help no longer separates candidates by cost (Goutham & Gu (2026)).
- **Course policy as a workforce-competency decision.** McCorkle's (2025) design case makes the trade-off explicit at task level: for each step of a semester project the instructor pairs an emerging GenAI workforce competency (prompting for objectives, generating images, writing scripts, text-to-speech narration) against the need to assess a foundational skill, and permits AI only where the competency wins. That is a concrete way to build the workflow skills employers value (Prompt Engineering, evaluation of LLM output) into existing assignments rather than adding a separate AI course.
- **AI already mediates career preparation itself.** Loidl, Cao and Huang (2026) surveyed 102 undergraduates at one Midwestern R1 university and found about 81% had used ChatGPT for employability-related activities in the previous 12 months, led by resumes (52.94%), workplace communication (38.24%), and cover letters (35.29%), which the interviews read as tailoring and rehearsal work rather than outsourcing; career readiness therefore has to be built on preparation that the tool already mediates, not only on the capacities this page otherwise describes.
- **The mode of use reorganizes what students count as employability.** In eight focus groups at one Madrid university (30 students), ChatGPT users credited efficiency, screening of AI suggestions and output refinement, while non-users credited deliberation, originality and teamwork — 8 of the 9 teamwork mentions came from non-users (Calle-Martinez et al. 2026). The authors name the two paths assisted autonomy and slow creativity, and caution that neither was measured.
- **Sector-specific readiness frameworks.** Workforce readiness for smart manufacturing and the future of the engineering/computing workforce translate general employability into discipline-specific competency frameworks.

- **What faculty expect AI to displace, and what that is not.** In ten interviews in an AI-focused engineering department, faculty disagreed about how generative AI would reshape work, naming coding, writing and information work as near-term vulnerable, while offering no labor-market evidence for those expectations (Sadik (2026)).
- **Workforce transitions.** The ICT career aspirations study examines how students' career intentions shift in response to technological change.
- **Theoretical grounding.** The AI Anxiety comprehensive analysis identifies the **fear of replacement by AI** as a primary driver of AI anxiety — the career dimension this concept addresses head-on.

Career readiness as a protective and developmental goal

A recurring theme is that career development in the AI era should be a **deliberate educational goal**, not an afterthought: building career adapt-abilities, core self-evaluations, Self-Efficacy, and employer-valued AI skills, while directly addressing the anxiety students feel about AI displacement. This links career development to Workplace Learning, Self-Efficacy, Motivation, and Anxiety and Stress, and positions education as both a skills pipeline and a source of psychological readiness.

Connections to related concepts

Career development and readiness connects to Workplace Learning (the vocational skills dimension), AI Literacy (the AI-competence dimension), Self-Efficacy and Motivation (the psychological resources that support adaptation), Anxiety and Stress (career anxiety as a key component), Higher Education and K-12 (the settings where readiness is built), and Student Experience (career concerns as part of the learner experience).

Common Misconceptions

- **"AI anxiety is a general disposition you can reassure away."** Duan et al. confirm with SEM that AI anxiety **impairs career decisions largely through eroded career adaptability (63.35% of the total effect)**. The mechanism is specific: anxiety works by removing the capacity to adapt, so reassurance aimed at feelings misses the mediator that carries the effect.
- **"Career adaptability is a soft skill secondary to technical competence."** Wang (2026) shows career adaptability **reduces AI anxiety**, which makes it an upstream intervention rather than a downstream outcome. Building adaptability addresses the mechanism; treating it as a nice-to-have leaves the mediator intact.
- **"Anxiety about AI is evenly distributed."** Üstün & Danacıoğlu find AI anxiety and negative AI attitudes predict post-graduation job-finding anxiety across **1,057 students**, with different patterns for **women and social-science students**. A uniform intervention misallocates support.

Lifelong Learning

> **Lifelong learning and AI** — how AI supports continuous education and skill development beyond formal schooling, and how it reshapes adult and workplace learning. AI can personalize, scaffold, and make learning-on-demand more accessible for adults, while also raising questions about autonomy, self-direction, and who controls the learning process in AI-mediated environments.

Questions to Consider

- Think about the last new skill you learned outside formal schooling — on the job, online, or self-taught. Who decided what to learn, how to learn it, and when you were 'done'? How would AI change that picture?
- A central question in the page is autonomy: as AI participates in identifying your learning needs, setting your goals, and even producing content, what remains genuinely self-directed in your own learning?
- Formal education treats time as fixed and curricula as sequential. The page proposes 'Learnity graphs' — interconnected units of knowledge learners navigate flexibly across a lifetime. What do you gain, and what do you risk losing, by freeing learning from a fixed sequence?
- AI can both support adult learners and change which skills adults must continuously update. If AI keeps reshaping your field, what capabilities would you invest in that no tool can simply give you?
- Lifelong learning is often framed as an individual's responsibility. But access across the lifespan is also an equity question. Who gets the time, resources, and support to keep learning as an adult — and how might AI widen or narrow that gap?

Introduction

Lifelong learning refers to continuous education throughout life — upskilling, reskilling, professional development, and informal learning beyond formal degrees. AI is increasingly central to this, both as a tool that supports adult learners and as a force that changes the skills adults must continually update.

How lifelong learning appears in the research

- **Design guidelines for adult learning:** Research from the AI-ALOE institute synthesizes empirically grounded design guidelines for AI-powered adult-learning technologies, emphasizing practical, context-sensitive support.
